Results of Geophysical Investigation Quest Diagnostics 7600 Tyrone Avenue Van Nuys, California

## Introduction

On May 17<sup>th</sup>, 2013, Spectrum Geophysics conducted a geophysical investigation on a portion of the Quest Diagnostics facility located in Van Nuys, California.

The purpose of the investigation was to delineate the surface trace of detectable steel underground storage tanks (USTs) within the area of investigation.

The area of investigation, as designated by Kristyn Drake of Alta Environmental, was soil covered and was roughly 1-acre in size.

Site interferences included reinforced concrete, bollards, chainlink fencing, large soil piles with debris, and scattered metallic surface debris.

## Methods

The equipment used in this investigation consisted of a Geonics EM-61 high-sensitivity metal detector, a shallow-focus metal detector (M-scope), and electromagnetic (EM) utility-locating equipment. A NavCom SF2050-G GPS unit and a digital field computer were used during EM-61 data acquisition.

## EM-61 High Sensitivity Metal Detector

The EM-61 high-sensitivity detector was used in an effort to delineate areas where metallic objects (such as underground storage tanks, and metal piping) may be buried. The EM-61 transmitter generates short pulses of electromagnetic energy that travel downward and outward and have a primary field associated with them. This energy becomes "trapped" in conductive materials and causes a secondary magnetic field to be generated in these materials. Between pulses, the receiver measures the voltage of the decay of this

EM-61 data acquisition (archive photo)

secondary magnetic field that is proportional to the conductivity of the subsurface materials.

Spectrum Geophysics 3

EM-61 readings were collected along roughly parallel lines spaced approximately 2.5 feet apart within the accessible areas of the investigation and stored concurrently with GPS eastings and northings in a digital field computer. These data were processed in the field and used to generate contour maps to assist in identifying anomalous areas that may be caused by buried metallic features.

## Electromagnetic (EM) Utility Location

Passive and active EM utility-locating methods were used in an effort to identify possible sources of EM-61 anomalies and to delineate the surface trace of detectable underground utilities and abandoned piping.

Electromagnetic (EM) utility location (archive photo)

Passive locating is possible when electrically

conductive conduits are energized by ambient radio frequencies (RF) that are often produced by 50/60 cycle electrical, radio, audio, television, and communication transmissions. A receiver tuned to these frequencies can be used to locate the re-radiated signal emitted by the conductor (i.e., conduit).

Active locating is initiated by conducting an EM signal at a known frequency (8 and 33 kHz for this site) on a conduit exposed at the surface. A receiver, tuned to these frequencies, is then used to locate the signal maxima (or surface trace) of the applied signal.

## Ground Penetrating Radar

EM-61 anomalies that could not be attributed to aboveground cultural features or detected underground conduits were further

Data collection using the Noggin GPR (archive photo)

investigated using GPR methods. GPR data were collected over suspect areas and interpreted in the field for anomalies whose signatures might indicate the presence of features of interest.

A high frequency radio signal is transmitted into the ground via the antenna. As radio waves propagate into the ground, these

Spectrum Geophysics 4

signals are reflected off structures with differing electrical properties. These reflected signals are then captured by the receiver and are presented as vertical profiles on the GPR unit.

The areal extents and/or surface traces of detected features were marked on the ground with spray paint.

#### Results

A map of the area of investigation is presented in Figure 1. A contour map of the EM-61 top coil data is presented in Figure 2.

#### EM-61

Fifteen distinct anomalies were observed on the EM-61 Top Coil Data contour map (Figure 2).

Anomaly A was located along Eastings 6428188 to 6428418 and between Northings 1899131 and 1829043. A gas line and a conduit were detected using EM utility-locating methods. Surface interference consisted of three steel drums, two concrete pads, a storm drain vault lid, a fence, and surface metallic debris that were observed in the area, however, they could not be determined as the sole sources of the anomaly. A storm channel was also noted in the area, however, because of depth limitations it could not be detected. GPR provided no further information as to a source.

Anomaly B was located along Eastings 6428311 to 6428325 and between Northings 1899066 and 1899052. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly C was located along Eastings 6428280 to 6428289 and between Northings 1898990 and 1898981. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly D was located along Eastings 6428276 to 6428289 and between Northings 1898962 and 1898949. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly E was located along Eastings 6428474 to 6428321 and between Northings 1898941 and 1898912. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly F was located along Eastings 6428373 to 6428390 and between Northings 1898944 and 1898916. A small buried metallic feature was detected using hand-held metal detection, however, it could not be verified as the sole source of the anomaly. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly G was located along Eastings 6428478 to 6428556 and between Northings 1899037 and 1899003. EM-utility locating methods and GPR provided no further information as to a source. The source(s) of this anomaly appear to be located in or beneath the soil/debris pile.

Anomaly H was located along Eastings 6428473 to 6428492 and between Northings 1898974 and 1898960. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly I was located along Eastings 6428455 to 6428396 and between Northings 1898930 and 1898915. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly J was located along Eastings 6428509 to 6428520 and between Northings 1898981 and 1898969. A small buried metallic feature was detected using hand held metal detection, however, it could not be verified as the sole source of the anomaly. EM-utility locating methods and GPR provided no further information as to a source although two conduits or possible footings may project to the south and one to the east as indicated by the linear trending (LT) anomalies.

Anomaly K was located along Eastings 6428529 to 6428549 and between Northings 1898971 and 1898956. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly L was located along Eastings 6428556 to 6428590 and between Northings 1899026 and 1829006. A storm channel was noted in the area, however, because of depth limitations it could not be detected. EM-utility locating methods and GPR provided no further information as to a source.

*Anomaly M* was located along Eastings 6428591 to 6428605 and between Northings 1898942 and 1898959. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly N was located along Eastings 6428569 to 6428588 and between Northings 1898951 and 1898940. EM-utility locating methods and GPR provided no further information as to a source.

Anomaly O was located along Eastings 6428590 to 6428610 and between Northings 1898938 and 1898907. EM-utility locating methods and GPR provided no further information as to a source.

Several linear trending anomalies (see lines labled LT on Figure 1) were observed on the EM-61 contour maps. EM utility-locating methods did not identify conduits as a source, however, that does not preclude their presence. Typically LT anomalies are indicative

of conduits or a linear metal bearing feature such as building footings, however, numerous sources could cause a similar anomaly and some of these anomaly trends are more complex as multiple sources are likely present.

The north-south trending anomalous area located on the easternmost portion of the site was caused by a conduit and the fence.

#### Recommendations

We recommend a safe excavation of all cited anomalous areas and linear trend anomalies (LT) to determine their respective source(s).

We also recommend removal of all soil piles and debris as well as the reinforced concrete slabs in order to resurvey using metal detection methods in an effort to identify detectable buried metallic features in these areas. No distinctive anomalies could be determined on the northwest section of the area (with exception of *Anomaly B*) due to the presence of the numerous reinforced concrete slabs and other metallic or metal bearing features on the surface.

#### Limitations

#### EM-61

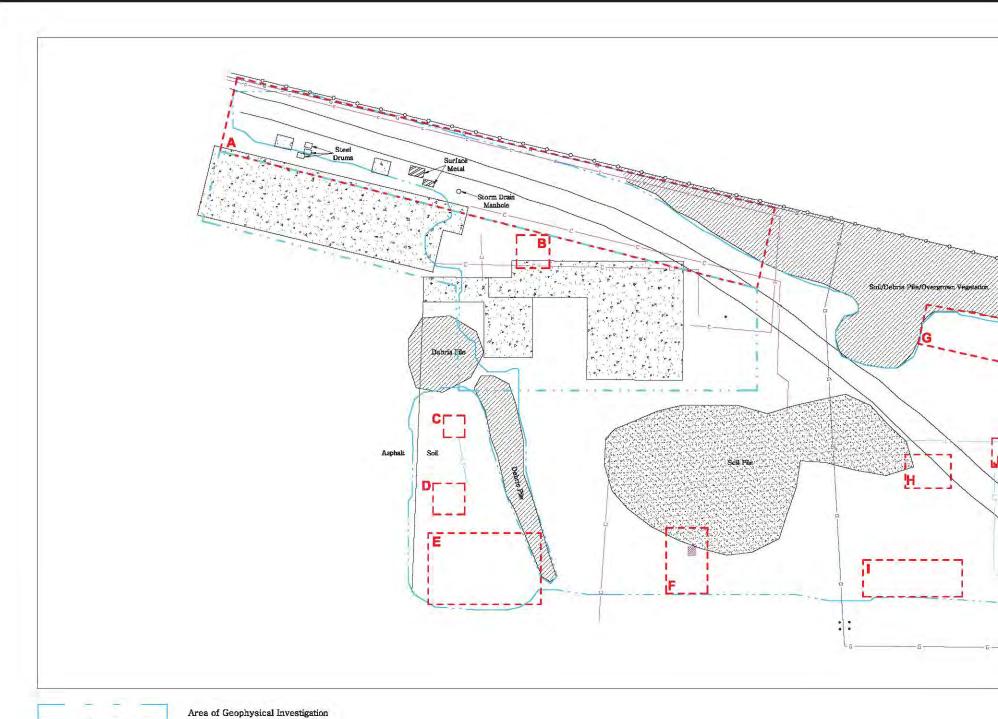

The EM-61 is capable of detecting a 55-gallon drum up to a depth of 3 meters under favorable conditions. We recommend a minimum 10-foot buffer between the survey area and any metallic or metal bearing surface cultural features such as cars, metal signs, or aboveground piping which could severely compromise the quality of the data. Reliable EM-61 data cannot be collected over areas covered with reinforced concrete.

#### General

It should be understood that the location of subsurface objects and utilities is dependent upon the recognition of physical phenomena at the ground surface. These phenomena can be magnetic fields or electro-magnetic waves that give rise to a surface expression which in turn is interpreted as representative of subsurface objects. These waves, however, may be attenuated and/or distorted by a number of factors including soil moisture, corrosion, and proximity to other surface and subsurface facilities.

Spectrum cannot provide interpretation for the presence or absence of USTs or other buried metallic features in areas where vehicles/dumpsters/surface metallic features or soil piles are

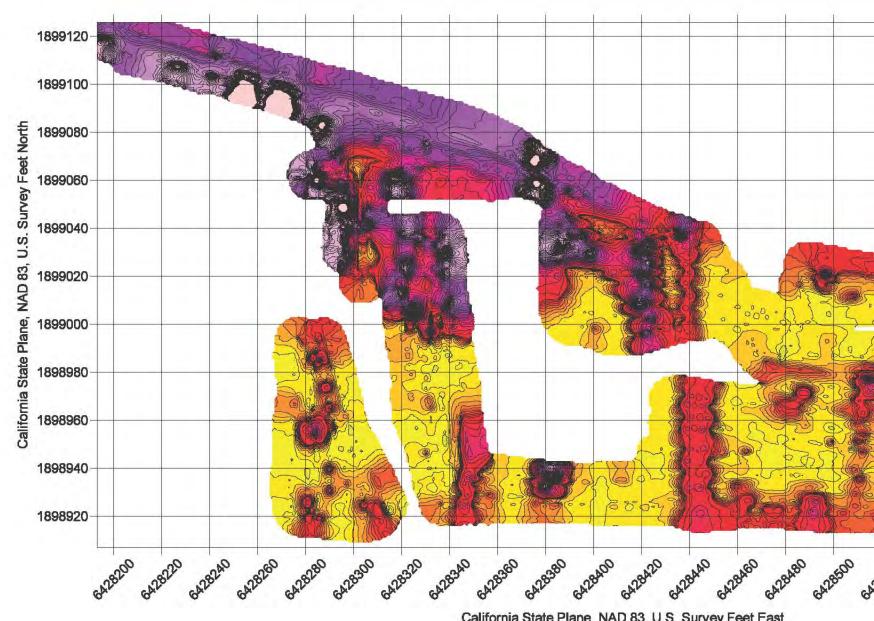

present. We recommend the surface area be cleared of potential interferences and resurveyed.

#### ENVIRONMENTAL LABORATORY DATA REPORT

7600 TYRONE AVE, VAN NUYS Soil Samples

Soil samples from 7600 Tyrone Ave, Van Nuys, were submitted to the Environmental Laboratory on May 28, 2013 for the determination of their Volatile Organic Compounds (VOC), Metals, Semi-Volatile Organic Compounds (SVOC), Total Extractable Petroleum Hydrocarbons (TEPH) including Motor Oil (MO) and Diesel Range Organic (DRO), Chlorinated Pesticides, Polychlorinated Biphenyls (PCBs), and Gasoline Range Organics (GRO) content.

Testing information including tests requested and test methods are listed below. All quality assurance data indicate that the results for these samples are of acceptable quality.

| Analysis<br>Requested | Method         | Results               | Analyzed by       |

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

#### Dear Kevin Han:

Enclosed are the results of analyses for samples received 05/30/13 09:50 with the Chain of Custody document. The samples were received in good condition, at 2.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.
