Subject:

FW: Tyrone Property - Shallow Soil and Soil Gas Investigation Executive Summary

Attachments: Tables_prelim.pdf; Figures_prelim.pdf; Tyrone EXECSummary_Prelim.pdf

Gary:

Here is the Executive Summary (along with tables and figures). Preliminary conclusions and recommendations are provided.

We are still waiting for analytical results from sampling completed two days ago (June 12) in the former septic tank area. We do not anticipate the pending results to change the conclusions or recommendations.

We should be able to have the completed final report a week or so after the final lab results are in.

Kelvin.

EXECUTIVE SUMMARY

Alta Environmental (Alta) conducted a Surface Soil and Soil Gas Investigation for the Los Angeles Department of Water and Power (LADWP) on the former Quest Diagnostics property located at 7600 Tyrone Avenue, Van Nuys, California (the "Site). The Site is unoccupied and is listed for sale as a commercial/industrial property. The purpose of the investigation was to assess potential hazardous substance contamination at the Site prior to site acquisition. A Site Location Map is provided as Figure 1.

Site Description

The Site was an unoccupied bioscience laboratory prior to the investigation and consisted of nine buildings, parking areas, facility equipment, and chemical and hazardous material storage areas on the western and central section of the Site, and a vacant field containing an abandoned residential dwelling, bunny house, construction equipment, and construction material storage areas on the eastern portion of the Site. During field implementation of the investigation, the building structures on the Site were under active asbestos and lead-based paint abatement and demolition. Historical uses at the Site included agricultural activities up to 1965, when the initial building construction began at the Site. A Site Layout is provided as Figure 2.

Previous Investigations

Past environmental investigations at the Site included a Phase I Environmental Site Assessment (ESA) prepared for Quest Diagnostics, Inc. (ODIC, October 22, 2010), a Phase I ESA prepared for Shubin-Nadal Realty Investors (AMEC, October 22, 2012a), and a Screening Level Phase II Investigation prepared for Shubin-Nadal Realty Investors (AMEC, September 28, 2012b).

Based on the results of the Phase I ESAs (ODIC, 2010 and AMEC, 2012a) and Screening Level Phase II Investigation (AMEC, 2012b) the following conclusions were made:

The soil vapor data do not suggest a significant release has occurred at the site that would require mitigation for commercial development. Soil sample data suggest metals are not present at concentrations indicative of environmental impact and generally are consistent with typical background concentrations. The few low concentrations of volatile organic compounds (VOCs) and relatively low and heavier end hydrocarbons detected in shallow soil do not suggest significant impacts are present in the areas investigated (AMEC, 2012).

Based on information obtained from other properties in the general site vicinity of the Site, the anticipated depth to groundwater beneath the site is assumed to be between 200 and 250 feet bgs (RWQCB's online Geotracker database).

Environmental Concerns and Investigation Objectives

The primary objective of this investigation was to assess any subsurface impacts to the soil and soil gas at the Site from former use as a bioscience laboratory, historical structures, and former agricultural use.

Shallow Soil Matrix and Soil Gas Sampling

On May 28 and 29, 2013, a total of 30 shallow borings (B1 – B30) were drilled at the Site. All soil borings were continuously cored from surface to the terminus depth of 3 feet bgs using a direct-push drill rig. Soil matrix samples were collected from each boring at 1, 2, and 3 feet bgs using a core sampler lined with acetate sleeves. Soil boring locations are presented in Figure 3.

Following sample collection, the sample containers were properly capped, sealed, labeled, and stored in a chilled ice chest for transport under chain-of-custody documentation for analysis or archiving to LADWP's State of California-certified laboratory (Certificate No. 1207) located in Los Angeles, California. All soil samples designated for volatile analysis were preserved using in-field preservation kits in accordance with EPA Method 5035. The 1 and 3 foot samples from each boring were variously analyzed for Title 22 Metals by EPA Method 6010B, organochlorine pesticides (OCPs) by EPA Method 8081A, polychlorinated biphenyls (PCBs) by EPA Method 8082, total petroleum hydrocarbons (TPH) by EPA Method 8015M, semivolatile organic compounds (SVOCs) by EPA Method 8270C, and VOCs by EPA Method 8260B. The 2 foot samples collected from each boring were archived at the laboratory. The shallow soil sampling and analysis plan is presented as Table 1.

On May 30 and 31, 2013 soil vapor probes were installed at 15 boring locations (VP1 through VP15) at 5 and 15 feet bgs. On June 4 and 5, 2013, the soil vapor probes were sampled and analyzed by Jones Environmental, Inc.'s on-site mobile laboratory. Samples were not collected from vapor probes at VP4 and VP5 due to inaccessibility from stockpiled demolition debris. On June 12, 2013, soil vapor probes were installed in boring location VP16 in the vicinity of the former septic tank/cesspool at 5 and 15 feet bgs. Following probe installation and a minimum 2 hours of equilibration time, the vapor probes at VP16 were sampled using SUMMA® canisters and analyzed by the Jones Environmental fixed laboratory.

All soil vapor samples collected for this investigation were analyzed for VOCs by EPA Method 8260B by Jones Environmental Laboratory. The soil vapor samples included 28 primary samples, two (2) purge volume samples, and three (3) field replicates for a total of 33 soil vapor samples. The soil gas sampling and analysis plan is presented as Table 2. Soil Gas boring locations are presented in Figure 3.

Preliminary Findings

The following surface soil sample results are presented in milligrams per kilogram (mg/kg) and micrograms per kilogram (ug/kg) as identified in Tables 3 through 8. The following soil gas sample results are presented in micrograms per liter (ug/L) as identified in Table 9. All soil gas sample results were available and reviewed for the preparation of the following summary with the exception of sample results for VP16 (collected and submitted June 12, 2013), which are still pending.

- No VOCs or PCBs were detected in any of the surface soil samples submitted for analysis.
- Surface soil samples variously exhibited detected concentrations of:
 - Title 22 Metals including antimony (not detected above the laboratory reporting limit [ND] to 4.2J mg/kg), barium (99 to 300 mg/kg), cadmium (1.8J to 4.1 mg/kg), chromium (10 to 23 mg/kg), cobalt (7.8 to 21 mg/kg), copper (7.7J to 22 mg/kg), lead (6.7 to 42 mg/kg), molybdenum (ND to 0.5J), nickel (12.3 to 24 mg/kg), vanadium (19 to 38 mg/kg), zinc (36 to 124 mg/kg), and mercury (ND to 0.048 mg/kg). In addition, silver was detected in one sample (B22-1') at 7.4J mg/kg;
 - SVOCs including benzo(g,h,i)perylene (ND to 0.11J mg/kg), butyl benzyl phthalate (ND to 0.29J mg/kg), and indeno(1,2,3-cd)pyrene (ND to 0.17J mg/kg). In addition, dibenzo(a,h)antrhacene and pentachlorophenol were detected in one sample (B21-1') at 0.099J mg/kg and 0.39J mg/kg, respectively;
 - OCPs including 2,4-DDD (ND to 36 ug/kg), 2,4-DDT (ND to 190 ug/kg), 4,4-DDE (ND to 740 ug/kg), 4,4-DDT (ND to 270 ug/kg), beta-hexachlorocyclohexane (beta-BHC; ND to 42 ug/kg), and toxaphene (ND to 2,400 ug/kg); and
 - TPH as total extractable petroleum hydrocarbons (TEPH; ND to 60.6 mg/kg [as motor oil]);
- Soil gas samples exhibited detected concentrations of VOCs including carbon tetrachloride (ND to 0.035 ug/L), chloroform (ND to 0.896 ug/L), Freon 113 (ND to 2.82 ug/L), tetrachloroethylene (PCE; ND

to 0.059 ug/L), and trichloroethylene (TCE; ND to 2.89 ug/L). In addition, 1,1-dichloroethene (1,1-DCE) was detected in one sample (VP13-15') at a concentration of 0.118 ug/L.

Preliminary Conclusions

Based on the shallow soil sample results and the available soil gas sample results at the time of this summary:

- Concentrations of Title 22 Metals and SVOCs in soil are below the Environmental Protection Agency's (EPA, Region 9) Regional Screening Levels (RSLs) developed for a commercial/industrial scenario.
- Concentrations of OCPs in soil are below the Office of Environmental Health Hazard Assessment (OEHHA) and the CalEPA (OEHHA/CalEPA, 2010) residential and commercial/industrial California Human Health Screening Levels (CHHSLs), with the exception of toxaphene detected in one sample (B16-3'; 2,400 ug/kg), which exceeded the commercial/industrial CHHSL of 1,800 ug/kg.
- Concentrations of TPH detected in soil are below the Los Angeles California Regional Water
 Quality Control Board's (LARWQCB) maximum soil screening levels above drinking water aquifers
 greater than 150 feet bgs (LARWQCB, Table 4-1, May 1996) for TPH as gasoline (1,000 mg/kg),
 TPH as diesel (10,000 mg/kg), and TPH as motor oil (50,000 mg/kg).
- Concentrations of VOCs detected in soil gas are below the OEHHA/EPA (2010) CHHSLs for shallow soil gas (engineered fill) in a commercial/industrial land use scenario, for carbon tetrachloride (0.21 ug/L), PCE (1.6 ug/L), and TCE (4.4 ug/L). No CHHSLs are documented by Cal/EPA, OEHHA for the VOCs 1,1-DCE, Freon 113, and chloroform in soil gas.

It should be noted that the RSLs, CHHSLs, and Maximum Soil Screening Levels have been used as a general comparison, and are not regulatory standards and/or acceptable concentrations. These levels are used as benchmark values to determine whether further assessment and evaluation of the constituents detected in soil and soil gas, are required for the Site.

Preliminary Recommendations

Based on available analytical data, and the findings of this investigation, additional assessment work is not warranted at this time. However, any unknown subsurface structures or potentially contaminated soil encountered during site demolition and construction should be investigated for potential hazardous substances impacts to the property.

Additional assessment around sample location B16 at 3 feet bgs (B16-3') may be warranted in order to define the lateral and vertical extent of OCP (toxaphene) impacts in the area as necessary, and where disturbance of shallow soil in that area is anticipated during any site redevelopment activities.

These recommendations are preliminary. Updated or supplemental recommendations may be given, based on any additional information that becomes available (pending soil gas data). Once all the data has been reviewed by Alta Environmental, the LADWP will be provided with the final investigation report, which will include a finalized executive summary and recommendations.

Project No. 12069-01

To:

Shubin Nadal Realty Investors

901 Dove Street, Suite 225

Newport Beach, California 92660

Attention:

Mr. William Shubin

Subject:

Preliminary Geotechnical Exploration for Proposed Office-Industrial Project at 7600

Tryone Avenue, Van Nuys, City of Los Angeles, California

At your request and authorization, NMG Geotechnical, Inc. (NMG) has conducted a geotechnical exploration for the proposed development at the subject site located at 7600 Tyrone Avenue, in Van Nuys in the City of Los Angeles, California. The site location is shown on Figure 1. The purpose of this exploration was to assess the onsite geotechnical conditions and provide preliminary geotechnical recommendations for project design, grading and construction.

Our geotechnical exploration was performed June 25 and 26, 2012, which included drilling, sampling and logging of fifteen hollow-stem-auger borings (H-1 through H-15) to depths ranging from 9 to 31.5. Two of the borings were used for onsite percolation testing. Laboratory testing was performed on selected soil samples to determine engineering soil properties.

Other than constraints typical for this area (e.g. seismicity), the primary geotechnical constraint at the site is a potentially collapsible soil layer ranging in thickness from 2 to 4 feet found in the upper 5 to 7.5 feet of Borings H-4 and H-5. However, these soils appear to be limited to a localized area within the vicinity of these borings. The site is not located in potential liquefaction or earthquake-induced landslide hazard zones. Near surface soil has low expansion potential. For typical low-rise commercial/industrial buildings the total post-construction settlement is not anticipated to exceed one-half inch and differential settlement is anticipated to be less than ¼ inch in a 40-foot span, provided recommended remedial grading is performed and existing site grades are not raised significantly. Therefore, conventional shallow foundations and slabs-on-grade will acceptable for the planned construction.

This report presents our findings, conclusions and preliminary recommendations for the proposed project. Upon the completion of grading, additional soil samples may need to be collected and tested to confirm the recommendations provided herein. Also, the future grading and foundation plans should be reviewed by the geotechnical consultant in light of this study to confirm that our recommended design parameters have been used, and to provide further recommendations, as needed.

If you have any questions regarding this report, please contact our office. We appreciate the opportunity to provide our services.

Respectfully submitted,

1.0 INTRODUCTION

1.1 Site Location and Proposed Development

The site is located in a commercial-industrial district at 7600 Tyrone Avenue, in Van Nuys, within the City of Los Angeles, California. The site bordered by railroad tracks that run along Cabrito Road on the north, by Tyrone Avenue and existing commercial properties on the west, by Hazeltine Avenue on the east, and by the extension of Saticoy Street and commercial properties on the south.

We understand that existing structures and improvements at the site will be demolished. The conceptual site plan shows three proposed new industrial buildings, associated driveways and parking lots, and Saticoy Avenue improvements. The buildings will be single level tilt up construction with some mezzanine space. Access to the site will be off an extension of Saticoy Avenue, which may also be extended further east in the future. We understand that future grades will not be significantly different that existing grades. Therefore, we have assumed that new fill loads will be minor.

1.2 Existing Site Conditions

The subject site is trapezoidal and approximately 16.4 acres with existing buildings having a footprint of over 172,000 square feet. The existing buildings, some of which are multi-story, are surrounded by paved driveways and parking lots; most were constructed in the mid-1960s with one building built in 1988. The eastern end of the site is a predominantly vacant dirt parcel containing three small buildings in the northwest corner. This entire property is relatively flat with local areas of grasses, weeds, and small stockpiles of soil and rubble in the vacant lot area. There are some relatively large trees at the site, especially in the west half around the primary building campus. The existing buildings are currently unoccupied.

1.3 Scope of Services

Our scope of services for this study included the following tasks:

- Review of geotechnical information pertaining to the subject site, including site geology, historic groundwater data, and seismic hazard maps.
- Site reconnaissance to identify the existing site conditions and marking of boring and test-pit locations.
- Coordination with Underground Service Alert and a private utility locating service (Utillocate) to identify and locate any underground utilities.
- Field exploration consisted of drilling, logging and sampling of fifteen hollow-stem-auger borings to depths of 9 to 31.5 feet. The borings were backfilled with cuttings and patched with cold patch asphalt concrete. Soils in the borings were sampled using a Modified California ring sampler (2.5-inch, inside-diameter, split-barrel). The sampler was driven with a 140-pound automatic hammer, free-falling 30 inches. We collected relatively undisturbed

120810

ring samples from the borings at 2.5- to 5-foot intervals. Representative bulk samples of onsite soils were collected from the hollow-stem auger cuttings. The sampling was used to assess the soil beneath the site, as well as to obtain a measure of resistance of the soil to penetration (recorded as blows-per-foot on the geotechnical boring logs). The boring logs are included in Appendix B.

- Percolation testing on two boring locations to measure percolation and infiltration rates based on accepted local percolation test procedures and requirements.
- Laboratory testing of selected samples to classify the onsite soils and evaluate in-situ
 moisture and density, maximum dry density and optimum moisture content, R-value, grainsize distribution, Atterberg limits, direct shear, consolidation, expansion index, and soil
 corrosivity. Test results are summarized in Appendix C. A corrosion engineer's report is
 also attached at the rear of Appendix C.
- Geotechnical evaluation and analysis of the compiled data in light of the planned project.
- Evaluation of faulting and seismicity in accordance with the 2010 California Building Code (CBC).
- Preparation of this report including our findings, conclusions, preliminary recommendations and accompanying illustrations.

NMG's expertise and scope of services did not include assessment of potential subsurface environmental contaminants or environmental health hazards.

2

2.0 GEOTECHNICAL FINDINGS

2.1 Geologic Setting

The subject site is located in the central San Fernando Valley portion of the Transverse Range province of Southern California. The San Fernando Valley is an east-west trending structural trough bounded to the north and south by active faulting along the southern edge of the San Gabriel and Santa Monica Mountains. The site is mapped by the state as underlain by young alluviul fan deposits (USGS 2005) generated by the Pacoima and Tujunga washes which originate in the adjacent San Gabriel Mountains. The underlying material is described as consisting of unconsolidated gravel, sand, silt and clay. Portions of the valley are also underlain by flood deposits of the Los Angeles River.

2.2 Regional Faulting and Seismicity

Regional Faults: The site is not located within a fault-rupture hazard zone as defined by the Alquist-Priolo Special Studies Zones Act (CDMG, 1999) and no evidence of active faulting was observed during this exploration.

Using the USGS computer program (USGS, 2002, updated 2008) and the site coordinates of 34.209 degrees north latitude and 118.442 degrees west longitude, the closest major active faults to the site are the Northridge Hills Fault (5.3 km), Verdugo Fault (6.1 km), Sierra Madre Fault (9.7 km), Hollywood Fault (12.9 km).

Seismicity: Sites in southern California are subject to seismic hazards of varying degrees depending upon the proximity, degree of activity, and capability of nearby faults. These hazards can be primary (i.e., directly related to the energy release of an earthquake such as surface rupture and ground shaking) or secondary (i.e., related to the effect of earthquake energy on the physical world, which can cause phenomena such as liquefaction and ground lurching). Since there are no active faults at the site, the potential for primary ground rupture is considered low. The primary seismic hazard for this site is ground shaking due to a future earthquake on one of the major regional active faults listed above.

The maximum moment magnitude for the controlling fault is 6.93 M_W, with peak ground accelerations of 0.48g (SDS/2.5) which would be generated from the Northridge Hills fault.

The site is not located within an area of potential liquefaction, as defined by the State's Seismic Hazard Mapping Act. The attached Site Location and Seismic Hazards Map (Figure 1) shows the approximate location of the site relative to seismic hazard zones, as shown on the State of California Seismic Hazard Zones Map for the Van Nuys Quadrangle (CDMG, 1998).

Secondary seismic hazards, such as tsunami and seiche, are considered low as the site is located more than 15 miles away from the ocean and is not located within a mapped Tsunami Inundation Zone, nor is the site located near any confined water storage facilities (e.g., open reservoirs, water tanks, etc.).

2.3 Geotechnical Conditions

NMG's exploration encountered approximately 2.5 to 7.5 feet of undocumented artificial fill overlaying the alluvial deposits of the site. The existing artificial fill generally consisted of yellowish brown to brown silty sand. The artificial fill materials encountered were medium dense to dense with blow-counts in the range of 7 to 34 blows/ft (California Ring Sampler blows). Field moisture content varied from approximately 1.3 percent to 12.6 percent, with an average of about 8 percent. The dry densities of the fill ranged from 105.6 to 126 pounds per cubic foot (pcf).

Most of the alluvium deposits at the site generally consisted of interlayered yellowish brown, olive brown, and brown sandy and clayey silts, and silty sands; with some poorly graded sands in local areas. Sandy and clayey silt soils were predominantly found in our borings, with silty sand layers found at depths of 20 to 25 feet in Borings H-5, H-7 trhough H-9, H-11, and H-12. The sandy and clayey silts were medium stiff to stiff with blow-counts ranging from 6 to 29 blows/ft. Field moisture content for these soils varied from 4.2 to 20.3 percent and the dry density ranged from 95.9 to 116.7 pcf. The silty sand soils were medium dense to dense with blow counts varying from 13 to 32 blows per foot; field moisture content varied from 3 to 19.3 percent, having dry densities ranging from 99.9 to 128.1 pcf. Groundwater was not encountered in our borings.

The engineering properties, based on the laboratory test results, used to characterize the subsfurface soils are presented in Section 2.4.

2.4 Laboratory Test Results

We tested representative samples of onsite soils collected during our field exploration to characterize their engineering properties in general conformance with applicable American Society for Testing and Materials (ASTM) standards. The laboratory test results from this study are provided in Appendix C. In-situ moisture content and dry density data are included on the geotechnical boring logs (Appendix B).

Results of the maximum dry density testing indicates that the silty sandy soils collected at depths of 0 to 5 feet in Borings H-1 and H-12 have maximum dry densities of approximately 122 and 120 pcf at optimum moisture contents of 10.5 and 10 percent, respectively.

Grain-size distribution and plasticity tests (Atterberg Limits) were conducted on samples considered representative of the alluvial and artificial fill soil in the upper 10 feet. The samples tested were generally classified as silty sands and sandy silts, with fine contents ranging from 27 to 70 percent. One sample in Boring H-1 and at depth of 7.5 feet was classified as a poorly graded sand with fine content of 4 percent. A representative artificial fill soil sample at a depth of 2.5 feet was found to be non-plastic. One clayey silt sample collected at a depth ranging from 5 to 10 feet was found to have a liquid limit of 27 percent and a plastic limit of 35 percent.

Based on laboratory testing, the onsite sandy and silty soils in the upper 10 feet have "low" to "very low" expansion potential (Expansion Index in the range of 8 to 22). The R-values of two near surface soil samples were 60 and 70.

Direct shear testing was conducted on two undisturbed alluvial samples and one undisturbed artificial fill sample representative of sandy and silty soils, collected at depths of feet, in order to evaluate the strength properties of the underlying materials. The results of the direct shear test indicate that the alluvial soils have an ultimate internal friction angle of 26 degrees with cohesion of 100 pounds per square foot (psf). The peak internal friction angle was 28 degrees at cohesion of 400 psf. The fill soil sample had an ultimate friction angle of 27 degrees at 175 cohesion; the peak values for friction angle and cohesion were 31 degrees and 350 psf, respectively.

The boring data and consolidation test results show that onsite soils have low to moderate settlement potential with the exception of some soil that may be prone to hydroconsolidation (collapse upon saturation). Soil samples tested from depths of 5 and 7.5 feet at borings H-4 and H-5, respectively showed collapse potentials ranging from from 1.86 to 4.21 percent upon the introduction of water at 3.2 ksf axial load. Two representative samples of the near-surface soils were sent to an outside laboratory for corrosivity testing. This testing included pH, soil resistivity, sulfate content and chloride content.

The electrical resistivity test on the saturated soil sample indicates that onsite soils are corrosive to ferrous metals. Sulfate-content test result indicates that onsite soils have "negligible" sulfate exposure per Table 4.3.1 of ACI-318. The corrosivity test results and the corrosion protection recommendation report prepared by HDR Schiff are presented in Appendix C.

2.5 Groundwater

Groundwater was not encountered in any of our borings to a depth of 31.5 feet. Historic high groundwater at the site is mapped at 70 to 80 feet below ground; however, local groundwater well data indicates it ould be as deep as 200 feet. Groundwater is not anticipated to be encountered during grading operations

2.6 Settlement

With the exception of the potentially collapsible soil discussed in Section 2.4, the soil at the site is has relatively low settlement potential for the anticipated fill and structural loads. Some of the near surface soil in the vacant portion of the site on the east end is looser and dry. Provided the recommended remedial measures herein are implemented the total consolidation (static) settlement for the proposed structures should not exceed 1/2- inch following construction. The differential settlement should not exceed 1/4-inch over a 40-foot span.

If not mitigated, the potential settlement related to the collapsible soil encountered in borings H-4 and H-5 is on the order of 1 to 2 inches. This assumes the collapsible soil layer is 2 to 4 feet thick and would become saturated following project completion (either from natural or maninduced infiltration). Because the limits of the collapsible soil can vary, the entire settlement

potential of 1 to 2 inches may be differential. This differs from differential settlements calculated from normal consolidation settlement which is often estimated as one half of the total settlement.

The soil characteristics at the site are such that the soil should not be prone to significant settlement that can be induced by earthquake related ground shaking.

2.7 Seismic Hazards

The site is not located within any mapped seismic hazard zone. We did not encounter conditions considered significant with respect to other secondary seismic hazards such as liquefaction.

2.8 Percolation Testing

Percolation testing at the site was performed on June 27, 2012. The Boring Percolation Test Procedure was used as described in "Low Impact Development Best Management Practice Guideline For Design, Investigation, And Reporting" by the County of Los Angeles Department of Public Works (LADPW, 2011). Two percolation tests were performed in borings H-3 and H-6 (8-inch diameter) with depths of 12.5 and 7.5 feet, respectively. The borings were presoaked overnight prior to testing. The percolation testing was performed over a six-hour period and the final measurement was used to calculate the preliminary design infiltration rate. Percolation test data sheets are provided in Appendix D.

Measured percolation and infiltration rates were calculated based on the results of the final measurements at each test location. Measured infiltration rates were calculated using the formula given in the Boring Percolation Test Procedure (LADPW, 2011). This equation corrects for vertical flow and removes the affects of lateral flow. Measured percolation rates and measured infiltration rates are given in Table 1, below.

TABLE	1 - PERCOLATION T	EST RESULTS
Boring No.	Measured Percolation Rate (in./hr.)	Measured Infiltration Rate (in./hr.)
H-3	24.0	3.08
H-6	4.80	1.50

NMG

3.0 CONCLUSION AND RECOMMENDATIONS

3.1 General Conclusion and Recommendation

Based on our study, the proposed project is considered feasible from a geotechnical standpoint provided the recommendations in this report are implemented during design, grading and construction. The site will require partial removal of existing artificial fill materials, as well as remedial grading to remove anticipated unsuitable soils and provide a compacted fill blanket to support the proposed improvements.

Our recommendations are based on the anticipated geotechnical conditions and should be verified during grading and construction. Additional soil testing and revised recommendations may be necessary if import fill is required and/or exposed geotechnical conditions vary significantly from the findings and interpretations presented in this report. Geotechnical observation and testing should be conducted during grading and construction operations. The recommendations in this report are considered minimum and may be superseded by more stringent requirements of others and/or the future geotechnical consultant of record.

3.2 Site Preparation and Earthwork

Site preparation and grading should be performed in accordance with the recommendations herein and the requirements of the City of Los Angeles. NMG's General Earthwork and Grading Specifications are included in Appendix F.

3.2.1 Site Demolition and Clearing

Prior to remedial grading and after demolition and removal of the existing improvements, deleterious materials and debris should be cleared from the site and disposed of offsite. Excavation for the removal of existing utilities and vegetation should be observed by the geotechnical consultant. Large roots, highly organic soils, existing foundations, pipelines and construction debris should be removed and should not be incorporated into new fills.

Soil that is disturbed as part of large excavations or removal of underground utilities and foundations should be observed and evaluated by the geotechnical consultant who should provide remedial recommendations. Excavations that require backfill should be properly documented and compacted under the observation and testing of the geotechnical consultant.

3.2.2 Protection of Existing Improvements and Utilities

Existing improvements and utilities at or adjacent to the site that are to be protected in place should be located and visually marked prior to demolition and grading operations. Excavations adjacent to improvements to be protected in-place or any utility easement should be performed with care, so as not to undermine existing foundations or destabilize the adjacent ground.

3.2.3 Remedial Grading Measures

Some of the near-surface soils including the existing artificial fill are expected to be disturbed and unsuitable for structural support following site demolition. The upper one to two feet of soil in the vacant areas at the east end of the site is also weathered and loose. These materials should be removed and recompacted (per Section 3.2.4). On average, remedial removals across the site should be on the order of 2 to 3 feet deep, with the exception of the collapsible soil area near borings H-4 and H-5. The existing soil in this area should be removed down to approximately 7.5 feet below existing ground and recompacted. The general area of potentially collapsible soil is show on Figure 3. The extent to which the collapsible soils extends laterally should be determined in the field during removals by the geotechnical consultant. Soil may be deemed to have insignificant collapse potential if it has an in-place soil with dry density near 110 pcf or a degree of saturation over 65 percent. Clayey or very clean sands may also be visually classified as having low collapse potential.

We recommend a minimum new fill blanket of 3 feet within the new building footprints. The removal bottoms should be reviewed and approved by the geotechnical consultant prior to placement of new fill. Because the recommended remedial removal depths are based on limited subsurface data, locally deeper removals may be required to establish competent removal bottoms based on observed field conditions.

Excavations for remedial removals deeper than 4 feet should be laid back at 1.5H:1V inclinations or flatter. Shallower excavations may consist of near vertical sides.

3.2.4 Fill Placement

Upon completion of remedial removals, the approved removal bottoms should be scarified a minimum of 6 inches. The removal bottoms and fill materials should be compacted to at least 90 percent of maximum dry density, as determined by ASTM Test Method D1557. Fill materials should be placed in loose lifts no thicker than 8 inches.

Fill materials should be relatively free of deleterious material. Crushed (recycled) asphalt concrete and PCC concrete may be used as fill materials. The existing fill soil and alluvium at the site should generally be suitable for re-use as compacted fill. The moisture content of new compacted fill soils should be placed at above the optimum moisture content within the compactable moisture range. Appropriate support equipment and other measures (e.g., mixing, stockpiling) may be needed to achieve the uniform and correct moisture content for placement of the fill. If the soils become extremely wet (during wet seasons), special measures for mixing and drying may be required that will need to be determined based on the field conditions.

3.2.5 Earthwork Shrinkage and Bulking

Due to the inherent variability of soil materials, earthwork volume changes are difficult to accurately quantify. Based on the gathered data and our experience with similar materials,

120810 8 NMG

we anticipate the near surface soil that is removed and recompacted will shrink on the order of zero to 5 percent. Since the site has been previously developed, little to no subsidence is anticipated from site earthwork equipment.

3.3 Seismic Design Parameters

The seismic design criteria based on the 2010 California Building Code (CBC) are as follows:

Selected Seismic Design Parameters from 2010 CBC	Seismic Design Values	Reference
Latitude	34.2094 North	
Longitude	118.4423 West	
Controlling Seismic Source	Northridge Hills Fault	USGS, 2008
Distance to the Controlling Seismic Source	3.2 Miles (5.2 km)	USGS, 2008
Site Class per Table 1613.5.2	D	USGS, 2011
Spectral Acceleration for Short Periods (Ss)	1.754 g	USGS, 2011
Spectral Accelerations for 1-Second Periods (S1)	0.612 g	USGS, 2011
Five-Percent Damped Design Spectral Response Acceleration at Short Periods (S _{DS}) from Equation 16-38 (Site Class D)	1.169 g	USGS, 2011
Five-Percent Damped Design Spectral Response Acceleration at 1-Second Period (S _{DI}) from Equation 16-39 (Site Class D)	0.612 g	USGS, 2011

3.4 Foundation Design

Shallow foundations and slab-on-grade floors should be feasible for the proposed structurers. Our exploration and laboratory testing suggests that expansive soil will not a significant issue for foundations and slabs-on-grade. Although one of two expansion index (EI) tests had an EI of just over 20, we anticipate that following site demolition and grading, the general EI for the site may be classified as less than 20. (Foundation and slabs on soil with EI's greater than 20 should be designed per the requirements of Section 1808.6 of the 2010 CBC.) The preliminary design parameters for wire-reinforced slabs are provided below; however, these parameters may need to be revised if different conditions are encountered during the grading.

The design of slabs and foundations is the purview of the project structural engineer based on the anticipated dead and live loads. The design of foundations should also consider the settlement as discussed in Section 3.6.

For preliminary design purposes, the net allowable bearing capacity for footings may be calculated based on the following equation:

qall = 1,000 D + 500 B + 500

where:

D = embedment depth of footing, in feet

B = width of footing, in feet

q_{all} = maximum allowable bearing pressure, not to exceed 3,000 psf.

If applicable, an effective plasticity index of 10 may be used for design of wire-reinforced slabs. Also, a soil subgrade reaction, k_s, of 150 pounds per cubic inch (pci) and soil modulus of elasticity, E_s, of 1,500 psi are recommended for design of foundations and slabs. The allowable bearing pressure may be increased by one-third for wind and seismic loading. The coefficient of resistance of 0.35 against sliding is considered appropriate. For isolated footings, we recommend minimum embedment of 18 inches below lowest adjacent grade.

3.5 Interior Slab Moisture Mitigation

In addition to geotechnical and structural considerations, the project owner should also consider moisture mitigation when designing and constructing slabs-on-grade. The intended use of the interior space, type of flooring, and the type of goods in contact with the floor may dictate the need for, and design of, measures to mitigate potential effects of moisture emission from and/or moisture vapor transmission through the slab. A vapor retarder or barrier is typical under the slab to help mitigate moisture transmission through slabs.

Guidelines by the American Concrete Institute (ACI) (302.1R-96) recommend that the vapor retarder be placed directly under the slab (sand layer not required). However, the location of the vapor retarder and the use of sand above it may also be subject to the owner's/builder's past successful practice. A minimum 10-mil thick vapor retarder is recommended where flooring and/or interior use requires floor slab water vapor control.

Concrete mix design and curing are also significant factors in mitigating slab moisture problems. Concrete with lower water/cement ratios results in denser, less permeable slabs. They also "dry" faster with regard to when flooring can be installed (reduced moisture emissions quantities and rates). Rewetting of the slab following curing should be avoided since this can result in additional drying time required prior to flooring installation. Proper concrete slab testing prior to flooring installation is also important.

The concrete mix design and the type and location of the vapor retarder should be determined in coordination with all parties involved in the finished product, including the project owner, architect, structural engineer, geotechnical consultant, concrete subcontractors, and flooring subcontractors.

3.6 Settlement Potential

Static and seismic settlements for the proposed structures are not expected to exceed ½-inch total and ¼-inch differential following completion of construction, provided the recommendations in this report are implemented for design, grading, and construction.

3.7 Lateral Earth Pressures

The recommended lateral earth pressures based on our limited subsurface exploration and for approved compacted soils in drained conditions are as follows:

Conditions	Level (pcf)	2:1 Slope (pcf)
Active	40	65
At-Rest	60	85
Passive	360	135 (sloping down)

In addition to the above lateral forces due to retained earth, the influence of surcharge due to other loads such as adjacent footings, vehicular traffic or lateral loads acting on the retaining wall, if any, should be considered during the design of retaining walls. Recommendations for drainage behind retaining walls are provided in the attached detail (Figure 3, rear of text).

To design an unrestrained retaining structure, such as a cantilever wall, the active earth pressure may be used. For a restrained retaining structure, such as a basement wall, loading docks or at restrained-wall corners, the at-rest pressure should be used. Passive pressure is used to compute lateral soil resistance developed against lateral structural movement. Further, for sliding resistance, the friction coefficient of 0.35 may be used at the concrete and soil interface. In addition, the passive resistance is taken into account only if it is ensured that the soil against embedded structures will remain intact with time. Drainage behind retaining walls should also be provided, unless hydrostatic forces are incorporated in wall design.

The seismic lateral earth pressure for level backfill may be estimated to be an additional 14 pcf for active and at-rest conditions. The earthquake soil pressure distribution is similar to active and at-rest pressure distributions and is added to the static pressures. For the active and at-rest conditions, the additional earthquake loading is zero at the top and maximum at the bottom.

3.8 Cement Type

Concrete mix design for structural concrete elements may be based on the "negligible" soluble sulfate category of Table 4.3.1 in ACI-318-318R-43. Other ACI guidelines for structural concrete are recommended. Additional sampling and testing at or near the completion of grading may be recommended if soil conditions are encountered that are significantly different than anticipated.

3.9 Soil Corrosivity

The corrosion protection recommendation report prepared by HDR Schiff is included in Appendix C of this report.

3.10 Vehicular Pavement

As discussed previously, the R-value of the near surface soil samples collected in our geotechnical study at the site were in the range of 60 to 70. For preliminary purposes using a traffic index (TI) of 5.0 for parking stalls, TI of 5.5 for drive areas, and TI of 6.0 for drive entries; and a design R-value of 50, we recommend the following pavement sections in accordance with the California Highway Design Manual. Because of the high R-value, a minimum section of 3 inches asphalt concrete (AC) over 6 inches of aggregate base (AB) applies for all cases. In addition, pavement sections for concrete unit pavers are provided in the event they are specified.

	T.I.= 5.0 Primarily Passenger and Light Duty Vehicles	T.I.= 5.5 Drive Aisles	T.I.= 6.0 Truck Traffic Areas
	3-inch AC/6-inch AB	3-inch AC/6inches AB	3-inch AC/6-inch AB
Pavement	5-inch Full Depth AC/	5.5-inch Full Depth AC/	6-inch Full Depth AC/
Section	Compacted Subgrade	Compacted Subgrade	Compacted Subgrade
Alternatives	80mm (3.15")	80mm	80mm
	PAVERS/6-inch AB	PAVERS/8-inch AB	PAVERS/8-inch AB

If higher traffic indices are determined when project plans are more complete, the above pavement sections should be reviewed and adjusted as necessary.

Pavement sections should be constructed in accordance with the requirements of Section 301 and 302 of the Standard Specifications of Public Works Construction (The Green Book). Prior to construction of pavement sections, the subgrade soils should be scarified to a minimum depth of 6 inches, moisture-conditioned as needed, and recompacted in place to a minimum of 90 percent relative compaction per ASTM D1557. If AC is placed directly over the subgrade soil, then the subgrade soil should be compacted to a minimum relative compaction of 95 percent. Subgrade should be firm and unyielding.

AB materials should be crushed aggregate or crushed miscellaneous base in accordance with The Green Book. AB should be free of deleterious materials, placed in 6- to 8-inch loose lifts, moisture-conditioned as necessary, and compacted to a minimum of 95 percent relative compaction per ASTM D1557. AC should also be compacted to 95 percent relative compaction.

PCC Section for Truck Loading Docks and Trash Bin Areas: We recommend that the truck loading dock and trash bin area pavements be a minimum of 6-inch-thick PCC slab over compacted subgrade. Reinforcement with No. 3 rebars, at least 18 inches on center, both ways,

NMG

is recommended. The soil subgrade should be compacted to a minimum 95 percent relative compaction per ASTM D1557.

Moisture and root barriers should be considered along the street pavements that are adjacent to unpaved medians and parkways with landscape and irrigation in order to minimize the potential for wetting of the street subgrade soils and pavement distress.

3.11 Other Site Concrete

We recommend that the "low" category be used during the preliminary design of the project site. Additional laboratory testing or field evaluation following the completion of grading operations should be performed to verify our preliminary recommendations.

TYPICAL RECOMMI			ON-STRUCT	TURAL CONC	RETE
Recommendations	Very Low (< 20)	Low (20 - 50)	Medium (51 – 90)	High (91 – 130)	Very High (> 130)
Slab Thickness (Min.): Nominal thickness except where noted.	4"	4"	4"	4"	4" Full
Subbase: Thickness of sand or gravel layer below concrete	N/A	N/A	Optional	2" - 4"	2" - 4"
Presaturation: Degree of optimum moisture content (opt.) and depth of saturation	Pre-wet Only	1.1 x opt. to 6"	1.2 x opt. to 12"	1.3 x opt. to 18"	1.4 x opt. to 24"
Joints: Maximum spacing of control joints. Joint should be ¼ of total thickness	10'	10'	8'	61	6
Reinforcement: Rebar or equivalent welded wire mesh placed near mid-height of slab	N/A	N/A	Optional (WWF 6 x 6 - W1.4xW1.4)	No. 3 rebar, 24" O.C. both ways or equivalent wire mesh	No. 3 rebar, 24" O.C. both ways
Restraint: Slip dowels across cold joints; between sidewalk and curb	N/A	N/A	Optional	Across cold joints	Across cold joints (and into curb)

3.12 Storm Water Treatment

No plans are currently available showing potential stormwater infiltration locations, or a proposed stormwater infiltration system; therefore the recommendations given in this section are preliminary and are based on limited percolation testing performed at two boring locations (see Figure 1). Additional percolation testing and analyses may be required at specific locations once plans showing proposed infiltration devices and locations are available.

The measured infiltration rate of 1.5 inches per hour represents the underlying soil in this area. A factor of safety of 2.0 should be used for design. Thus, a preliminary design infiltration rate of 0.75 inches per hour is recommended for the preliminary design of a stormwater treatment system.

The infiltration system should be sized and designed by a qualified engineer and adhere to local guidelines and regulations pertaining to treatment and infiltration of onsite stormwater. Special care should be taken so as to limit damage or disturbance to onsite soils in a manner that may affect infiltration in the area of the proposed infiltration system.

3.13 Trench Excavation and Backfill

Excavations should be performed in accordance with the requirements set forth by Cal/OSHA Excavation Safety Regulations (Construction Safety Orders, Section 1504, 1539 through 1547, Title 8, California Code of Regulations). In general, onsite soils are anticipated to be classified as Type "C" due to the low cohesion and sandy character. Cal/OSHA regulations apply to excavations that are up to 20 feet deep.

Trenches, including interior utility, should be either backfilled with native soil and compacted to 90 percent relative compaction, or backfilled with clean sand (SE 30 or better), which can be densified with water jetting and flooding (except for sewer and water lines under the jurisdiction of IRWD, which does not typically allow jetting of sands).

Trenches excavated on a graded slope-face, if any, for utility or irrigation lines and/or for any purpose should be properly backfilled and compacted in order to obtain a minimum 90 percent relative compaction to the slope face. Trenches excavated next to structures and foundations should also be properly backfilled and compacted to provide full lateral support and reduce settlement potential.

3.14 Drainage and Irrigation

Inadequate control of run-off water, heavy irrigation after development of the site, or regional groundwater level changes may result in shallow groundwater conditions where previously none existed. Maintaining adequate surface drainage, proper disposal of run-off water, and control of irrigation will help reduce the potential for future moisture-related problems and differential movements from soil heave/settlement.

Surface drainage should be carefully taken into consideration during grading, landscaping, and building construction. Positive surface drainage should be provided to direct surface water away from structures and slopes and toward the street or suitable drainage devices. Ponding of water adjacent to the structures should not be allowed. Paved areas should be provided with adequate drainage devices, gradients, and curbing to prevent run-off flowing from paved areas onto adjacent unpaved areas.

The performance of foundations is also dependent upon maintaining adequate surface drainage away from structures. The minimum gradient within 5 feet of the buildings will depend upon surface landscaping. In general, we suggest that unpaved turf and landscape areas have a minimum gradient of 2 percent away from structures.

Construction of planter areas immediately adjacent to structures should be avoided. If planter boxes are constructed adjacent to or near buildings, the sides and bottoms of the planter should be provided with a moisture barrier to prevent penetration of the irrigation water into the subgrade. Provisions should be made to drain excess irrigation water from the planters without saturating the subgrade below or adjacent to the planters. Raised planter boxes may be drained with weepholes. Deep planters (such as palm tree planters) should be drained with below-ground, water-tight drainage lines connected to a suitable outlet.

3.15 Future Geotechnical Plan Reviews

Future plans for the proposed project and the grading plan should be reviewed and accepted by the geotechnical consultant. Additional exploration, recommendations or modifications to the recommendations herein may be necessary at that time depending on the final plans. The geotechnical consultant should also review the foundation plans for conformance with the geotechnical design parameters and evaluate the foundation design impacts on total and differential settlement for the structures at the site.

3.16 Observation and Testing during Grading and Construction

Geotechnical observation and testing should be performed by the geotechnical consultant of record during the following phases of grading and construction:

- During site preparation and clearing,
- During excavations to remove existing foundations and underground improvements;
- During earthwork, including observation and acceptance of remedial removal bottoms and fill placement;
- Following the completion of grading, in order to verify soil properties for foundations, slabon-grade and pavements;
- · Upon completion of any foundation or structural excavation, prior to pouring concrete;
- · During slab and flatwork subgrade preparation prior to pouring of concrete;
- During placement of backfill for utility trenches;
- During placement of backfill for retaining structures;
- During installation and backfill of subdrainage systems (if any);
- During subgrade preparation and placement of aggregate base and asphaltic concrete; and

15

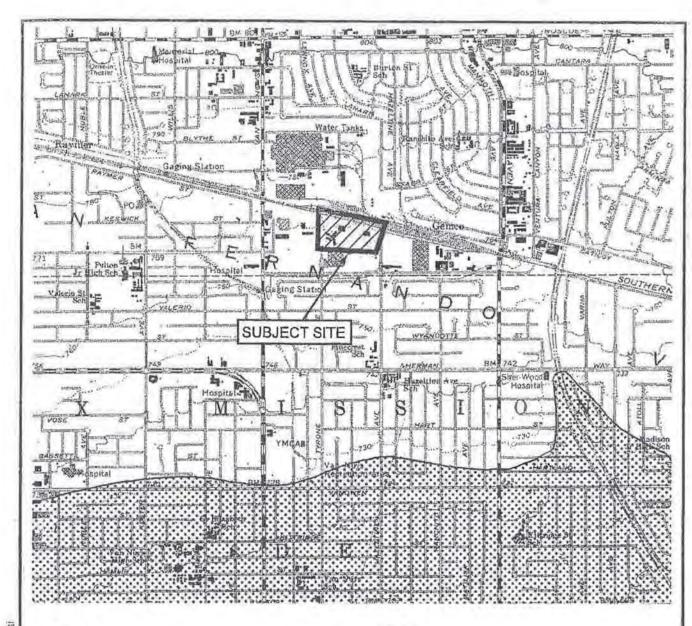

When any unusual soil conditions are encountered.

3.17 Limitations

This report has been prepared for the exclusive use of our client, Shubin Nadal Realty Investors, within the scope of services requested by our client for the specific project in Van Nuys described herein. This report or its contents should not be used or relied upon for other projects or purposes, or by other parties without the acknowledgement of NMG and the consultation of a geotechnical professional. The means and methods used by NMG for this study are based on local geotechnical standards of practice, care, and requirements of governing agencies. No warranty or guarantee, expressed or implied, is given.

Our findings, conclusions, and recommendations are professional opinions based on interpretations and inferences made from geologic and engineering data from specific locations and depths, observed or collected at a given time. By nature, geologic conditions can vary from point to point, can be very different in-between exploration points, and can also change over time. Our conclusions and recommendations are, by nature, preliminary and subject to verification and/or modification by NMG during grading and construction when more subsurface data is exposed.

Liquefaction

Areas where historic occurrence of liquefaction, or local geological, geotechnical and groundwater conditions indicate a potential for permanent ground displacements such that mitigation as defined in Public Resources Code Section 2693(c) would be required.

Earthquake-Induced Landslides

Areas where previous occurance of landslide movement, or local topographic, geotogical, geotochnical and aubsurface water conditions indicate a potential for permanent ground displacements such that mitigation as defined in Public Resources Code Section 2693(c) would be required.

SITE LOCATION AND SEISMIC HAZARDS MAP

BASE: U.S.G.S. SEISMIC HAZARDS MAP, VAN NUYS QUADRANGLE Dated: February 1, 1998

Project Name: Shubin Nadal/Van Nuys

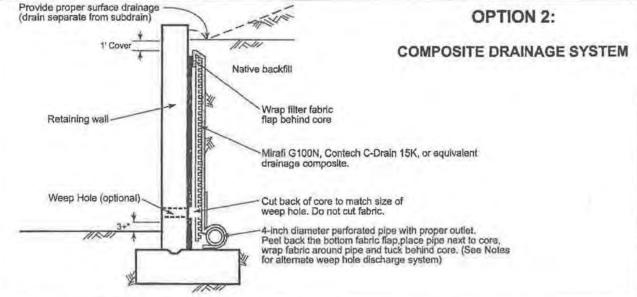

Date: 8-10-12

Figure No. 1

NMG Georechnical, Inc.

NOTES

- PIPE TYPE SHOULD BE PVC OR ABS, SCHEDULE 40 OR SDR35 SATISFYING THE REQUIREMENTS OF ASTM TEST STANDARD D1527, D1785, D2751, OR D3034.
- 2. FILTER FABRIC SHALL BE APPROVED PERMEABLE NON-WOVEN POLYESTER, NYLON, OR POLYPROPYLENE MATERIAL.
- 3. DRAIN PIPE SHOULD HAVE A GRADIENT OF 1 PERCENT MINIMUM.
- 4. WATERPROOFING MEMBRANE MAY BE REQUIRED FOR A SPECIFIC RETAINING WALL (SUCH AS A STUCCO OR BASEMENT WALL).
- 5. WEEP HOLES MAY BE PROVIDED FOR LOW RETAINING WALLS (LESS THAN 3 FEET IN HEIGHT) IN LIEU OF A VERTICAL DRAIN AND PIPE AND WHERE POTENTIAL WATER FROM BEHIND THE RETAINING WALL WILL NOT CREATE A NUISANCE WATER CONDITION. IF EXPOSURE IS NOT PERMITTED, A PROPER SUBDRAIN OUTLET SYSTEM SHOULD BE PROVIDED.
- 6. IF EXPOSURE IS PERMITTED, WEEP HOLES SHOULD BE 2-INCH MINIMUM DIAMETER AND PROVIDED AT 25-FOOT MAXIMUM SPACING ALONG WALL. WEEP HOLES SHOULD BE LOCATED 3+ INCHES ABOVE FINISHED GRADE.
- SCREENING SUCH AS WITH A FILTER FABRIC SHOULD BE PROVIDED FOR WEEP HOLES/OPEN JOINTS TO PREVENT EARTH MATERIALS FROM ENTERING THE HOLES/JOINTS.
- OPEN VERTICAL MASONRY JOINTS (I.E., OMIT MORTAR FROM JOINTS OF FIRST COURSE ABOVE FINISHED GRADE) AT 32-INCH MAXIMUM INTERVALS MAY BE SUBSTITUTED FOR WEEP HOLES.
- 9 THE GEOTECHNICAL CONSULTANT MAY PROVIDE ADDITIONAL RECOMMENDATIONS FOR RETAINING WALLS DESIGNED FOR SELECT SAND BACKFILL.

RETAINING WALL DRAINAGE DETAIL

Sampler and Symbol Descriptions

- Modified California sample (63.5 mm diameter)
- Standard Penetration Test
- Undisturbed pushed tube sample
- Large bulk sample
- Small bulk sample
- * Approximate depth of perched water or groundwater

Note: Number of blows required to advance driven sample 300 mm (or length noted) is recorded; blow count recorded for seating interval (initial 150 mm of drive) is indicated by an asterisk.

Laboratory and Field Test Abbreviations

MD Laboratory compaction test
CN Laboratory consolidation test

DS Laboratory direct shear test

AL Atterberg limits

SE Sand Equivalent

GS Grain Size Analysis (Sieve and/or Hydro.)

RV R-Value

CC Chemical Testing incl. Soluble Sulfate

El Expansion Index

UU Unconsolidated Shear Strength

GENERAL NOTES

- 1. Station location is indicated with offset to right (R) or left (L) of centerline (CL).
- Soil classifications are based on the Unified Soil System and include color, moisture, and relative density or consistency. Field
 descriptions have been modified to reflect results of laboratory tests where deemed appropriate. Bedrock descriptions are based on visual
 classification and include rock type, moisture, color, grain size, strength, and weathering.
- Descriptions on these boring logs apply only at the specific boring locations and at the time the borings were made. They are not warranted to be representative of subsurface conditions at other locations or times.

Re:

Soil Corrosivity Study Shubin Nadal/Van Nuys Van Nuys, California

HDR Schiff #12-0612SCS, HDR #188782

NMG #12069-01

### INTRODUCTION

Laboratory tests have been completed on two soil samples provided for the Shubin Nadal/Van Nuys project. The purpose of these tests was to determine if the soils might have deleterious effects on underground utility piping and concrete structures. HDR Engineering, Inc. (HDR|Schiff) assumes that the samples provided are representative of the most corrosive soils at the site.

The proposed construction consists of an office-industrial building. The site is located at 7600 Tyrone Avenue in Van Nuys, California. The water table is reportedly not encountered during boring explorations 32 feet deep.

The scope of this study is limited to a determination of soil corrosivity and general corrosion control recommendations for materials likely to be used for construction. Our recommendations do not constitute, and are not meant as a substitute for, design documents for the purpose of construction. If the architects and/or engineers desire more specific information, designs, specifications, or review of design, HDR|Schiff will be happy to work with them as a separate phase of this project.

### LABORATORY SOIL CORROSIVITY TESTS

The electrical resistivity of each sample was measured in a soil box per ASTM G187 in its asreceived condition and again after saturation with distilled water. Resistivities are at about their lowest value when the soil is saturated. The pH of the saturated samples was measured per CTM 643. A 5:1 water:soil extract from each sample was chemically analyzed for the major soluble salts commonly found in soil per ASTM D4327 and D6919. Test results are shown in Table 1.

### SOIL CORROSIVITY

A major factor in determining soil corrosivity is electrical resistivity. The electrical resistivity of a soil is a measure of its resistance to the flow of electrical current. Corrosion of buried metal is an electrochemical process in which the amount of metal loss due to corrosion is directly proportional to the flow of electrical current (DC) from the metal into the soil. Corrosion currents, following Ohm's Law, are inversely proportional to soil resistivity. Lower electrical resistivities result from higher moisture and soluble salt contents and indicate corrosive soil.

A correlation between electrical resistivity and corrosivity toward ferrous metals is:1

Soil Resistivity in ohm-centimeters Greater than 10,000 2,000 to 10,000 1,000 to 2,000 0 to 1,000

Corrosivity Category
Mildly Corrosive
Moderately Corrosive
Corrosive
Severely Corrosive

Other soil characteristics that may influence corrosivity towards metals are pH, soluble salt content, soil types, aeration, anaerobic conditions, and site drainage.

Electrical resistivities were in the mildly and moderately corrosive categories with as-received moisture. When saturated, the resistivities were in the moderately corrosive and corrosive categories. The resistivities dropped considerably with added moisture because the samples were dry as-received.

Soil pH values varied from 7.6 to 7.8. This range is mildly alkaline.<sup>2</sup> These values do not particularly increase soil corrosivity.

The soluble salt content of the samples was low.

The nitrate concentration was high enough to be aggressive to copper,

Tests were not made for sulfide and negative oxidation-reduction (redox) potential because these samples did not exhibit characteristics typically associated with anaerobic conditions.

This soil is classified as corrosive to ferrous metals and aggressive to copper.

<sup>&</sup>lt;sup>2</sup> Romanoff, Melvin. Underground Corrosion, NBS Circular 579. Reprinted by NACE. Houston, TX, 1989, p. 8.

### CORROSION CONTROL RECOMMENDATIONS

The life of buried materials depends on thickness, strength, loads, construction details, soil moisture, etc., in addition to soil corrosivity, and is, therefore, difficult to predict. Of more practical value are corrosion control methods that will increase the life of materials that would be subject to significant corrosion.

The following recommendations are based on the soil conditions discussed in the Soil Corrosivity section above. Unless otherwise indicated, these recommendations apply to the entire site or alignment.

### Steel Pipe

Implement all the following measures:

- Underground steel pipe with rubber gasketed, mechanical, grooved end, or other nonconductive type joints should be bonded for electrical continuity. Electrical continuity is necessary for corrosion monitoring and cathodic protection.
- Install corrosion monitoring test stations to facilitate corrosion monitoring and the application of cathodic protection;
  - At each end of the pipeline.
  - b. At each end of all casings.
  - c. Other locations as necessary so the interval between test stations does not exceed 1,200 feet.
- To prevent dissimilar metal corrosion cells and to facilitate the application of cathodic protection, electrically isolate each buried steel pipeline per NACE Standard SP0286 from:
  - a. Dissimilar metals.
  - b. Dissimilarly coated piping (cement-mortar vs. dielectric).
  - c. Above ground steel pipe.
  - d. All existing piping.
- Choose one of the following corrosion control options:

### OPTION 1

- a. Apply a suitable dielectric coating intended for underground use such as:
  - Polyurethane per AWWA C222 or
  - ii. Extruded polyethylene per AWWA C215 or
  - iii. A tape coating system per AWWA C214 or
  - iv. Hot applied coal tar enamel per AWWA C203 or
  - v. Fusion bonded epoxy per AWWA C213.
- Apply cathodic protection to steel piping as per NACE Standard SP0169.

### OPTION 2

a. As an alternative to dielectric coating and cathodic protection, apply a ¾-inch cement mortar coating per AWWA C205 or encase in concrete 3 inches thick, using any type of cement. Joint bonds, test stations, and insulated joints are still required for these alternatives.

NOTE: Some steel piping systems, such as for oil, gas, and high-pressure piping systems, have special corrosion and cathodic protection requirements that must be evaluated for each specific application.

### Iron Pipe

Implement all the following measures:

- Electrically insulate underground iron pipe from dissimilar metals and from above ground iron pipe with insulating joints per NACE Standard SP0286.
- Bond all nonconductive type joints for electrical continuity. Electrical continuity is necessary for corrosion monitoring and cathodic protection.
- Install corrosion monitoring test stations to facilitate corrosion monitoring and the application of cathodic protection:
  - a. At each end of the pipeline.
  - b. At each end of any casings.
  - Other locations as necessary so the interval between test stations does not exceed 1,200 feet.
- 4. Choose one of the following corrosion control options:

### OPTION 1

- a. Apply a suitable coating intended for underground use such as:
  - i. Polyethylene encasement per AWWA C105; or
  - ii. Epoxy coating; or
  - iii. Polyurethane; or
  - iv. Wax tape.

NOTE: The thin factory-applied asphaltic coating applied to ductile iron pipe for transportation and aesthetic purposes does not constitute a corrosion control coating.

 Apply cathodic protection to cast and ductile iron piping as per NACE Standard SP0169.

#### OPTION 2

a. As an alternative to coating systems described in Option 1 and cathodic protection, concrete encase all buried portions of metallic piping so that there is a minimum of 3 inches of concrete cover provided over and around surfaces of pipe, fittings, and valves using any type of cement.

# Copper Tubing

Protect buried copper tubing by one of the following measures:

- 1. Prevention of soil contact. Soil contact may be prevented by placing the tubing above ground or encasing the tubing using PVC pipe with solvent-welded joints.
- Installation of a factory-coated copper pipe with a minimum 25-mil thickness such as Kamco's Aqua Shield™, Mueller's Streamline Protec™, or equal. The coating must be continuous with no cuts or defects.
- Installation of 12-mil polyethylene pipe wrapping tape with butyl rubber mastic over a suitable primer. Protect wrapped copper tubing by applying cathodic protection per NACE Standard SP0169.

### Plastic and Vitrified Clay Pipe

- No special precautions are required for plastic and vitrified clay piping placed underground from a corrosion viewpoint.
- Protect all metallic fittings and valves with wax tape per AWWA C217 or epoxy.

### All Pipe

- On all pipes, appurtenances, and fittings not protected by cathodic protection, coat bare metal such as valves, bolts, flange joints, joint harnesses, and flexible couplings with wax tape per AWWA C217 after assembly.
- Where metallic pipelines penetrate concrete structures such as building floors, vault walls, and thrust blocks use plastic sleeves, rubber seals, or other dielectric material to prevent pipe contact with the concrete and reinforcing steel.

### Concrete

- From a corrosion standpoint, any type of cement may be used for concrete structures and pipe because the sulfate concentration is negligible, 0 to 0.1 percent.<sup>3,4,5</sup>
- Standard concrete cover over reinforcing steel may be used for concrete structures and pipe in contact with these soils due to the low chloride concentration<sup>6</sup> found onsite.

#### APPENDIX F

#### GENERAL EARTHWORK AND GRADING SPECIFICATIONS

#### 1.0 General

- 1.1 Intent: These General Earthwork and Grading Specifications are for the grading and earthwork shown on the approved grading plan(s) and/or indicated in the geotechnical report(s). These Specifications are a part of the recommendations contained in the geotechnical report(s). In case of conflict, the specific recommendations in the geotechnical report shall supersede these more general Specifications. Observations of the earthwork by the project Geotechnical Consultant during the course of grading may result in new or revised recommendations that could supersede these specifications or the recommendations in the geotechnical report(s).
- 1.2 Geotechnical Consultant: Prior to commencement of work, the owner shall employ a geotechnical consultant. The geotechnical consultant shall be responsible for reviewing the approved geotechnical report(s) and accepting the adequacy of the preliminary geotechnical findings, conclusions, and recommendations prior to the commencement of the grading.

Prior to commencement of grading, the Geotechnical Consultant shall review the "work plan" prepared by the Earthwork Contractor (Contractor) and schedule sufficient personnel to perform the appropriate level of observation, mapping, and compaction testing.

During the grading and earthwork operations, the Geotechnical Consultant shall observe, map, and document the subsurface exposures to verify the geotechnical design assumptions. If the observed conditions are found to be significantly different than the interpreted assumptions during the design phase, the Geotechnical Consultant shall inform the owner, recommend appropriate changes in design to accommodate the observed conditions, and notify the review agency where required. Subsurface areas to be geotechnically observed, mapped, elevations recorded, and/or tested include natural ground after it has been cleared for receiving fill but before fill is placed, bottoms of all "remedial removal" areas, all key bottoms, and benches made on sloping ground to receive fill.

The Geotechnical Consultant shall observe the moisture-conditioning and processing of the subgrade and fill materials and perform relative compaction testing of fill to determine the attained level of compaction. The Geotechnical Consultant shall provide the test results to the owner and the Contractor on a routine and frequent basis.

1.3 The Earthwork Contractor: The Earthwork Contractor (Contractor) shall be qualified, experienced, and knowledgeable in earthwork logistics, preparation and processing of ground to receive fill, moisture-conditioning and processing of fill, and compacting fill. The Contractor shall review and accept the plans, geotechnical report(s), and these Specifications prior to commencement of grading. The Contractor shall be solely responsible for performing the grading in accordance with the plans and specifications.

The Contractor shall prepare and submit to the owner and the Geotechnical Consultant a work plan that indicates the sequence of earthwork grading, the number of "spreads" of work and the estimated quantities of daily earthwork contemplated for the site prior to commencement of grading. The Contractor shall inform the owner and the Geotechnical Consultant of changes in work schedules and updates to the work plan at least 24 hours in advance of such changes so that appropriate observations and tests can be planned and accomplished. The Contractor shall not assume that the Geotechnical Consultant is aware of all grading operations.

The Contractor shall have the sole responsibility to provide adequate equipment and methods to accomplish the earthwork in accordance with the applicable grading codes and agency ordinances, these Specifications, and the recommendations in the approved geotechnical report(s) and grading plan(s). If, in the opinion of the Geotechnical Consultant, unsatisfactory conditions, such as unsuitable soil, improper moisture condition, inadequate compaction, insufficient buttress key size, adverse weather, etc., are resulting in a quality of work less than required in these specifications, the Geotechnical Consultant shall reject the work and may recommend to the owner that construction be stopped until the conditions are rectified.

#### 2.0 Preparation of Areas to be Filled

2.1 <u>Clearing and Grubbing</u>: Vegetation, such as brush, grass, roots, and other deleterious material shall be sufficiently removed and properly disposed of in a method acceptable to the owner, governing agencies, and the Geotechnical Consultant.

The Geotechnical Consultant shall evaluate the extent of these removals depending on specific site conditions. Earth fill material shall not contain more than 1 percent of organic materials (by volume). No fill lift shall contain more than 5 percent of organic matter. Nesting of the organic materials shall not be allowed.

If potentially hazardous materials are encountered, the Contractor shall stop work in the affected area, and a hazardous material specialist shall be informed immediately for proper evaluation and handling of these materials prior to continuing to work in that area.

As presently defined by the State of California, most refined petroleum products (gasoline, diesel fuel, motor oil, grease, coolant, etc.) have chemical constituents that are considered to be hazardous waste. As such, the indiscriminate dumping or spillage of these fluids onto the ground may constitute a misdemeanor, punishable by fines and/or imprisonment, and shall not be allowed.

- 2.2 Processing: Existing ground that has been declared satisfactory for support of fill by the Geotechnical Consultant shall be scarified to a minimum depth of 6 inches. Existing ground that is not satisfactory shall be overexcavated as specified in the following section. Scarification shall continue until soils are broken down and free of large clay lumps or clods and the working surface is reasonably uniform, flat, and free of uneven features that would inhibit uniform compaction.
- 2.3 Overexcavation: In addition to removals and overexcavations recommended in the approved geotechnical report(s) and the grading plan, soft, loose, dry, saturated, spongy, organic-rich, highly fractured or otherwise unsuitable ground shall be overexcavated to competent ground as evaluated by the Geotechnical Consultant during grading.
- 2.4 <u>Benching</u>: Where fills are to be placed on ground with slopes steeper than 5:1 (horizontal to vertical units), the ground shall be stepped or benched. Please see the Standard Details for a graphic illustration. The lowest bench or key shall be a minimum of 15 feet wide and at least 2 feet deep, into competent material as evaluated by the Geotechnical Consultant. Other benches shall be excavated a minimum height of 4 feet into competent material or as otherwise recommended by the Geotechnical Consultant. Fill placed on ground sloping flatter than 5:1 shall also be benched or otherwise overexcavated to provide a flat subgrade for the fill.
- 2.5 Evaluation/Acceptance of Fill Areas: All areas to receive fill, including removal and processed areas, key bottoms, and benches, shall be observed, mapped, elevations recorded, and/or tested prior to being accepted by the Geotechnical Consultant as suitable to receive fill. The Contractor shall obtain a written acceptance from the Geotechnical Consultant prior to fill placement. A licensed surveyor shall provide the survey control for determining elevations of processed areas, keys, and benches.

#### 3.0 Fill Material

- 3.1 General: Material to be used as fill shall be essentially free of organic matter and other deleterious substances evaluated and accepted by the Geotechnical Consultant prior to placement. Soils of poor quality, such as those with unacceptable gradation, high expansion potential, or low strength shall be placed in areas acceptable to the Geotechnical Consultant or mixed with other soils to achieve satisfactory fill material.
- 3.2 Oversize: Oversize material defined as rock, or other irreducible material with a maximum dimension greater than 12 inches, shall not be buried or placed in fill unless location, materials, and placement methods are specifically accepted by the Geotechnical Consultant. Placement operations shall be such that nesting of oversized material does not occur and such that oversize material is completely surrounded by compacted or densified fill. Oversize material shall not be placed within 10 vertical feet of finish grade or within 2 feet of future utilities or underground construction.
- 3.3 Import: If importing of fill material is required for grading, proposed import material shall meet the requirements of Section 3.1. The potential import source shall be given to the Geotechnical Consultant at least 48 hours (2 working days) before importing begins so that its suitability can be determined and appropriate tests performed.

#### 4.0 Fill Placement and Compaction

- 4.1 <u>Fill Layers</u>: Approved fill material shall be placed in areas prepared to receive fill (per Section 3.0) in near-horizontal layers not exceeding 8 inches in loose thickness. The Geotechnical Consultant may accept thicker layers if testing indicates the grading procedures can adequately compact the thicker layers. Each layer shall be spread evenly and mixed thoroughly to attain relative uniformity of material and moisture throughout.
- 4.2 <u>Fill Moisture Conditioning</u>: Fill soils shall be watered, dried back, blended, and/or mixed, as necessary to attain a relatively uniform moisture content at or slightly over optimum. Maximum density and optimum soil moisture content tests shall be performed in accordance with the American Society of Testing and Materials (ASTM Test Method D1557-91).
- 4.3 <u>Compaction of Fill</u>: After each layer has been moisture-conditioned, mixed, and evenly spread, it shall be uniformly compacted to not less than 90 percent of maximum dry density (ASTM Test Method D1557-91). Compaction equipment shall be adequately sized and be either specifically designed for soil compaction or of proven reliability to efficiently achieve the specified level of compaction with uniformity.

- 4.4 <u>Compaction of Fill Slopes</u>: In addition to normal compaction procedures specified above, compaction of slopes shall be accomplished by backrolling of slopes with sheepsfoot rollers at increments of 3 to 4 feet in fill elevation, or by other methods producing satisfactory results acceptable to the Geotechnical Consultant. Upon completion of grading, relative compaction of the fill, out to the slope face, shall be at least 90 percent of maximum density per ASTM Test Method D1557-91.
- 4.5 <u>Compaction Testing</u>: Field tests for moisture content and relative compaction of the fill soils shall be performed by the Geotechnical Consultant. Location and frequency of tests shall be at the Consultant's discretion based on field conditions encountered. Compaction test locations will not necessarily be selected on a random basis. Test locations shall be selected to verify adequacy of compaction levels in areas that are judged to be prone to inadequate compaction (such as close to slope faces and at the fill/bedrock benches).
- 4.6 Frequency of Compaction Testing: Tests shall be taken at intervals not exceeding 2 feet in vertical rise and/or 1,000 cubic yards of compacted fill soils embankment. In addition, as a guideline, at least one test shall be taken on slope faces for each 5,000 square feet of slope face and/or each 10 feet of vertical height of slope. The Contractor shall assure that fill construction is such that the testing schedule can be accomplished by the Geotechnical Consultant. The Contractor shall stop or slow down the earthwork construction if these minimum standards are not met.
- 4.7 <u>Compaction Test Locations</u>: The Geotechnical Consultant shall document the approximate elevation and horizontal coordinates of each test location. The Contractor shall coordinate with the project surveyor to assure that sufficient grade stakes are established so that the Geotechnical Consultant can determine the test locations with sufficient accuracy. At a minimum, two grade stakes within a horizontal distance of 100 feet and vertically less than 5 feet apart from potential test locations shall be provided.

#### 5.0 Subdrain Installation

Subdrain systems shall be installed in accordance with the approved geotechnical report(s), the grading plan, and the Standard Details. The Geotechnical Consultant may recommend additional subdrains and/or changes in subdrain extent, location, grade, or material depending on conditions encountered during grading. All subdrains shall be surveyed by a land surveyor/civil engineer for line and grade after installation and prior to burial. Sufficient time should be allowed by the Contractor for these surveys.

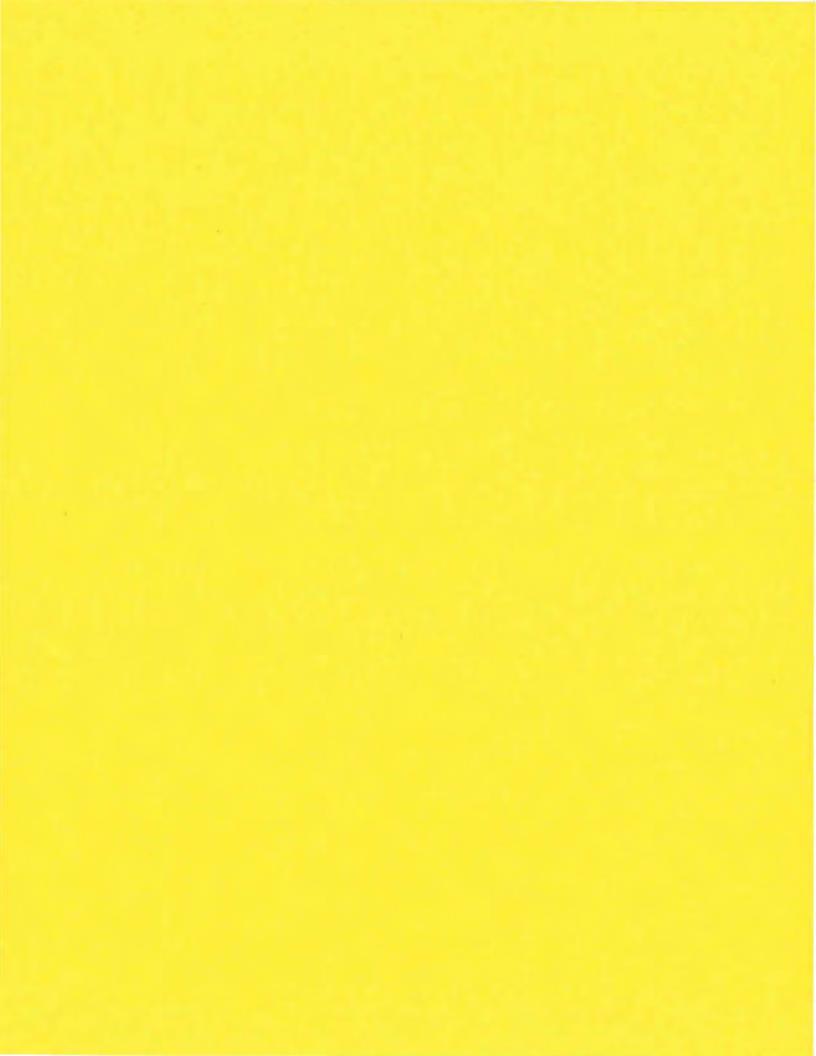

#### 6.0 Excavation

Excavations, as well as over-excavation for remedial purposes, shall be evaluated by the Geotechnical Consultant during grading. Remedial removal depths shown on geotechnical plans are estimates only. The actual extent of removal shall be determined by the Geotechnical Consultant based on the field evaluation of exposed conditions during grading. Where fill-over-cut slopes are to be graded, the cut portion of the slope shall be made, evaluated, and accepted by the Geotechnical Consultant prior to placement of materials for construction of the fill portion of the slope, unless otherwise recommended by the Geotechnical Consultant.

#### 7.0 Trench Backfills

- 7.1 Contractor shall follow all OHSA and Cal/OSHA requirements for safety of trench excavations.
- 7.2 Bedding and backfill of utility trenches shall be done in accordance with the applicable provisions of Standard Specifications of Public Works Construction. Bedding material shall have a Sand Equivalent greater than 30 (SE>30). The bedding shall be placed to 1 foot over the top of the conduit and densified by jetting. Backfill shall be placed and densified to a minimum 90 percent of maximum from 1 foot above the top of the conduit to the surface, except in traveled ways (see Section 7.6 below).
- 7.3 Jetting of the bedding around the conduits shall be observed by the Geotechnical Consultant.
- 7.4 Geotechnical Consultant shall test the trench backfill for relative compaction. At least one test should be made for every 300 feet of trench and 2 feet of fill.
- 7.5 Lift thickness of trench backfill shall not exceed those allowed in the Standard Specifications of Public Works Construction unless the Contractor can demonstrate to the Geotechnical Consultant that the fill lift can be compacted to the minimum relative compaction by his alternative equipment and method.
- 7.6 Trench backfill in the upper foot measured from finish grade within existing or future traveled way, shoulder, and other paved areas (or areas to receive pavement) should be placed to a minimum 95 percent relative compaction.

#### ENVIRONMENTAL LABORATORY DATA REPORT

#### 7600 TYRONE AVE, VAN NUYS Soil Samples

Soil samples from 7600 Tyrone Ave, Van Nuys, were submitted to the Environmental Laboratory on May 28, 2013 for the determination of their Volatile Organic Compounds (VOC), Metals, Semi-Volatile Organic Compounds (SVOC), Total Extractable Petroleum Hydrocarbons (TEPH) including Motor Oil (MO) and Diesel Range Organic (DRO), Chlorinated Pesticides, Polychlorinated Biphenyls (PCBs), and Gasoline Range Organics (GRO) content.

Testing information including tests requested and test methods are listed below. All quality assurance data indicate that the results for these samples are of acceptable quality.

| Analysis<br>Requested | Method         | Results               | Analyzed<br>by    |
|-----------------------|----------------|-----------------------|-------------------|
| VOC                   | EPA 8260 B     | Attachment #1         | Environmental Lab |

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narretive. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

#### Dear Kevin Han:

Enclosed are the results of analyses for samples received 05/30/13 09:50 with the Chain of Custody document. The samples were received in good condition, at 2.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

#### Notes and Definitions

\$-11 Surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogate.

MS-05 The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS

and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.

J Detected but below the Reporting Limit; therefore, result is an estimated concentration.

NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)

dry Sample results reported on a dry weight basis

RPD Relative Percent Difference

% Rec Percent Recovery

Sub Subcontracted analysis, original report available upon request

MDL Method Detection Limit

MDA Minimum Detectable Activity

MRL Method Reporting Limit

NR Not Reportable

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

# ENVIRONMENTAL LABORATORY DATA REPORT

7600 TYRONE AVE, VAN NUYS Soil Samples

Soil samples from 7600 Tyrone Ave, Van Nuys, were submitted to the Environmental Laboratory on May 29, 2013 for the determination of their Volatile Organic Compounds (VOC), Metals, Semi-Volatile Organic Compounds (SVOC), Total Extractable Petroleum Hydrocarbons (TEPH) including Motor Oil (MO) and Diesel Range Organic (DRO), Chlorinated Pesticides, Polychlorinated Biphenyls (PCBs), and Gasoline Range Organics (GRO) content.

Testing information including tests requested and test methods are listed below. All quality assurance data indicate that the results for these samples are of acceptable quality.

| Analysis<br>Requested | Method         | Results       | Analyzed<br>by    |
|-----------------------|----------------|---------------|-------------------|
| VOC                   | EPA 8260 B     | Attachment #1 | Environmental Lab |
| Metals                | EPA 6010B/7471 | Attachment #2 | Environmental Lab |
| TEPH/Diesel/Motor Oil | EPA 8015M      | Attachment #3 | Environmental Lab |
| GRO                   | EPA 8015B      | Attachment #4 | Environmental Lab |
| PCB                   | EPA 8082       | Attachment #5 | Weck Laboratories |
| Pesticides            | EPA 8081A      | Attachment #6 | Weck Laboratories |
| SVOC                  | EPA 8270 C     | Attachment #7 | Weck Laboratories |

This report has been updated to include Pesticide Analyses (EPA 8081A- Attachment #6). The report was also revised as the MDL for Mercury Analysis in the original report was listed in parts per billion (ug/kg) instead of parts per million (mg/kg).

Additionally, please not that VOC analyses in Attachment #1 include results for this project from COC-1321 as well.

If you have any questions, or if further information is required, please contact Mr. Jeremy Stoa at (213) 367-7266 or Mr. Kevin Han at (213) 367-7267.

ND - Not Detected; below method detection limit

MDL - Method Detection Limit

PQL - Practical Quantitation Limit (5 x MDL)

J - Geater than MDL, but less than PQL

ACP % = Acceptable Range of Percent

% RC = % Recovery

<sup>\*\*</sup> Sample was analyzed at higher dilution: Sample extract was either exhibiting high turbidity or highly colored MDL/PQL at higher dilution is calculted as MDL/PQL (dilution x1) multipled by the dilution factor

#### NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

#### Dear Kevin Han:

Enclosed are the results of analyses for samples received 05/30/13 09:50 with the Chain of Custody document. The samples were received in good condition, at 2.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualiflers.

#### Notes and Definitions

M-08 Due to the high concentration of analyte inherent in the sample, sample was diluted prior to preparation. The MDL and MRL were raised

due to this dilution

Detected but below the Reporting Limit; therefore, result is an estimated concentration.

NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)

dry Sample results reported on a dry weight basis

RPD Relative Percent Difference

% Rec Percent Recovery

Sub Subcontracted analysis, original report available upon request

MDL Method Detection Limit

MDA Minimum Detectable Activity

MRL Method Reporting Limit

Not Reportable

NR

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Colliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

## NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

#### Dear Kevin Han:

Enclosed are the results of analyses for samples received 05/30/13 09:50 with the Chain of Custody document. The samples were received in good condition, at 2.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

Notes and Definitions

Surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogate. S-11

The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS MS-05

and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.

Detected but below the Reporting Limit; therefore, result is an estimated concentration.

NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL) ND

Sample results reported on a dry weight basis dry

Relative Percent Difference RPD

Percent Récovery % Rec

Sub Subcontracted analysis, original report available upon request

Method Detection Limit MDL

Minimum Detectable Activity MDA

Method Reporting Limit MRL

Not Reportable NR

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

#### ANALYSES REQUESTED

1. EPA 8260B - Volatile Organics by GC/MS + Oxygenates

Sampling – Soil Gas samples were collected in glass gas-tight syringes equipped with Teflon plungers. Tubing placed in the ground for soil gas sampling was purged three different times as recommended by DTSC/RWQCB regulations. This purge test determined how many purges of the soil gas tubing were needed throughout the project. One, three and ten purge volumes were analyzed to make this determination.

A tracer gas mixture of n-propanol and n-pentane was placed at the tubing-surface interface before sampling. These compounds were analyzed during the 8260B analytical run to determine if there were surface leaks into the subsurface due to improper installation of the probe. No n-propanol or n-pentane was found in any of the samples reported herein.

The sampling rate was approximately 200 cc/min except when noted differently on the chain of custody record using a gas tight syringe. 1 purge volume was used since this purging level gave the highest results for the compound(s) of greatest interest.

Prior to purging and sampling of soil gas at each point, a shut-in test was conducted to check for leaks in the above ground fittings. The shut-in test was performed on the above ground apparatus by evacuating the line to a vacuum of 100 inches of water, sealing the entire system and watching the vacuum for some length of time. A vacuum gauge attached in parallel to the apparatus measured the vacuum. If there was any observable loss of vacuum, the fittings were adjusted as needed until the vacuum did not change noticeably. The soil gas sample was then taken.

Analytical – Soil Gas samples were analyzed using EPA Method 8260 that includes extra compounds required by DTSC/RWQCB (such as Freon 113). Instrument Continuing Calibration Verification, QC Reference Standards, Instrument Blanks and Sampling Blanks were analyzed every 12 hours as prescribed by the method. In addition, Matrix Spike (MS) and Matrix Spike Duplicates (MSD) were analyzed with each batch of Soil Gas samples. A duplicate/replicate sample was analyzed each day of the sampling activity.

All samples were analyzed within 30 minutes of sampling.

## JONES ENVIRONMENTAL LABORATORY RESULTS

Client: Client Address: Alta Environmental, Inc 3777 Long Beach Blvd.

Long Beach, CA 90807

Attn: Steve Morrill

Project: Tyrone
Project Address: 7600 Tryone Ave.

Van Nuys, CA

Report date: 6/4/2013

JEL Ref. No.: A-7098 Client Ref. No.: ODWP-13-1198

Date Sampled: 6/4/2013 Date Received: 6/4/2013

Date Analyzed: 6/4/2013 Physical State: Soil Gas

## EPA 8260B-Volatile Organics by GC/MS + Oxygenates

Re: Surface Soil and Soil Gas Sampling Report, Tyrone Site, 7600 Tyrone Avenue, Van Nuys, California 91405

Alta Environmental Project No. LDWP-13-1198

Dear Mr. Faeustle:

Alta Environmental is pleased to present the Surface Soil and Soil Gas Sampling Report for the Tyrone Site. Please refer to the report for our findings and conclusions.

If you have any questions, please call me at (562) 495-5777.

For and on behalf of Alta Environmental

Steve Morrill, PE

Senior Project Manager/Engineer III

# SURFACE SOIL AND SOIL GAS SAMPLING REPORT

Tyrone Site 7600 Tyrone Avenue Van Nuys, California 91405

Prepared for

City of Los Angeles Department of Water and Power Environmental Affairs 111 N. Hope Street, Room 1050 Los Angeles, California, 90012

Senior Project Manager/Senior Engineer III

#### **EXECUTIVE SUMMARY**

Alta Environmental (Alta) conducted a Surface Soil and Soil Gas Investigation for the Los Angeles
Department of Water and Power (LADWP) on the former Quest Diagnostics property located at 7600
Tyrone Avenue, Van Nuys, California (the "Site). The Site is unoccupied and is listed for sale as a
commercial/industrial property. The purpose of the investigation was to assess potential hazardous
substance contamination at the Site prior to site acquisition. A Site Location Map is provided as Figure 1.

#### **Site Description**

The Site was an unoccupied bioscience laboratory prior to the investigation and consisted of nine buildings, parking areas, facility equipment, and chemical and hazardous material storage areas on the western and central section of the Site, and a vacant field containing an abandoned residential dwelling, bunny house, construction equipment, and construction material storage areas on the eastern portion of the Site. During field implementation of the investigation, the building structures on the Site were under active asbestos and lead-based paint abatement and demolition. Historical uses at the Site included agricultural activities up to 1965, when the initial building construction began at the Site. A Site Layout is provided as Figure 2.

#### **Previous Investigations**

Past environmental investigations at the Site included a Phase I Environmental Site Assessment (ESA) prepared for Quest Diagnostics, Inc. (ODIC, October 22, 2010), a Phase I ESA prepared for Shubin-Nadal Realty Investors (AMEC, August 22, 2012a), and a Screening Level Phase II Investigation prepared for Shubin-Nadal Realty Investors (AMEC, September 28, 2012b).

Based on the results of the Phase I ESAs (ODIC, 2010 and AMEC, 2012a) and Screening Level Phase II Investigation (AMEC, 2012b) the following conclusions were made:

- The soil gas data do not suggest a significant release has occurred at the site that would require
  mitigation for commercial development. Soil sample data suggest metals are not present at
  concentrations indicative of environmental impact and generally are consistent with typical background
  concentrations. The few low concentrations of volatile organic compounds (VOCs) and relatively low
  and heavier end hydrocarbons detected in shallow soil do not suggest significant impacts are present
  in the areas investigated (AMEC, 2012b).
- Based on information obtained from other properties in the general site vicinity of the Site, the
  anticipated depth to groundwater beneath the site is assumed to be between 200 and 250 feet below
  ground surface (bgs) (Regional Water Quality Control Board's [RWQCB's] online Geotracker
  database).

#### **Environmental Concerns and Investigation Objectives**

The primary objective of this investigation was to assess any subsurface impacts to the soil and soil gas at the Site from former use as a bioscience laboratory, historical structures, and former agricultural use.

#### Shallow Soil Matrix and Soil Gas Sampling

On May 28 and 29, 2013, a total of 30 shallow borings (B1 – B30) were drilled at the Site. All soil borings were continuously cored from surface to the terminus depth of 3 feet bgs using a direct-push drill rig. Soil matrix samples were collected from each boring at 1, 2, and 3 feet bgs using a core sampler lined with acetate sleeves. Soil boring locations are presented in Figure 3.

Following sample collection, the sample containers were properly capped, sealed, labeled, and stored in a chilled ice chest for transport under chain-of-custody documentation for analysis or archiving to LADWP's State of California-certified laboratory (Certificate No. 1207) located in Los Angeles, California. All soil samples designated for volatile analysis were preserved using in-field preservation kits in accordance with EPA Method 5035. The 1 and 3 foot samples from each boring were variously analyzed for Title 22 Metals by EPA Method 6010B, organochlorine pesticides (OCPs) by EPA Method 8081A, polychlorinated biphenyls (PCBs) by EPA Method 8082, total petroleum hydrocarbons (TPH) by EPA Method 8015M, semivolatile organic compounds (SVOCs) by EPA Method 8270C, and VOCs by EPA Method 8260B. The shallow soil sampling and analysis plan is presented as Table 1.

On May 30 and 31, 2013 soil gas probes were installed at 15 boring locations (VP1 through VP15) at 5 and 15 feet bgs. On June 4 and 5, 2013, the soil gas probes were sampled and analyzed by Jones Environmental, Inc.'s on-site mobile laboratory. Samples were not collected from gas probes at VP4 and VP5 due to inaccessibility from stockpiled demolition debris.

On June 12, 2013, soil gas probes were installed in boring location VP16 in the vicinity of the former septic tank/cesspool at 5 and 15 feet bgs. Following probe installation and a minimum 2 hours of equilibration time, the gas probes at VP16 were sampled using SUMMA® canisters and analyzed by Jones Environmental's fixed laboratory.

All soil gas samples collected for this investigation were analyzed for VOCs by EPA Method 8260B by Jones Environmental Laboratory. The soil gas samples included 28 primary samples, two (2) purge volume samples, and three (3) field replicates for a total of 33 soil gas samples. The soil gas sampling and analysis plan is presented as Table 2. Soil gas boring locations are presented in Figure 3.

#### **Findings**

The following surface soil sample results are presented in milligrams per kilogram (mg/kg) and micrograms per kilogram (µg/kg) as identified in Tables 3 through 8. The following soil gas sample results are presented in micrograms per liter (µg/L) as identified in Table 9. Some data have been qualified by the laboratory as "J-flagged" indicating that the detected concentration is an estimated value between the method detection limit (MDL) and the practical quantitation limit (PQL).

- No VOCs or PCBs were detected in any of the surface soil samples submitted for analysis.
- Surface soil samples variously exhibited detected concentrations of:
  - Title 22 Metals including antimony (not detected above the laboratory reporting limit [ND] to 4.2J mg/kg), barium (99 to 300 mg/kg), cadmium (1.8J to 4.1 mg/kg), chromium (10 to 23 mg/kg), cobalt (7.8 to 21 mg/kg), copper (7.7J to 22 mg/kg), lead (6.7 to 42 mg/kg), molybdenum (ND to 0.50J mg/kg), nickel (12.3 to 24 mg/kg), vanadium (19 to 38 mg/kg), zinc (36 to 124 mg/kg), and mercury (ND to 0.048 mg/kg). In addition, silver was detected in one sample (B22-1') at 7.4J mg/kg;
  - SVOCs including benzo(g,h,i)perylene (ND to 0.11J mg/kg), butyl benzyl phthalate (ND to 0.29J mg/kg), and indeno(1,2,3-cd)pyrene (ND to 0.17J mg/kg). In addition, dibenzo(a,h)antrhacene and pentachlorophenol were detected in one sample (B21-1') at 0.099J mg/kg and 0.39J mg/kg, respectively;

- OCPs including 2,4-DDD (ND to 36 μg/kg), 2,4-DDT (ND to 190 μg/kg), 4,4-DDE (ND to 740 μg/kg), 4,4-DDT (ND to 270 μg/kg), beta-hexachlorocyclohexane (beta-BHC; ND to 42 μg/kg), and toxaphene (ND to 2,400 μg/kg); and
- TPH as total extractable petroleum hydrocarbons (TEPH; ND to 60.6 mg/kg [as motor oil]);
- Soil gas samples exhibited detected concentrations of VOCs including carbon tetrachloride (ND to 0.035 μg/L), chloroform (ND to 0.896 μg/L), Freon 113 (ND to 2.82 μg/L), tetrachloroethylene (PCE; ND to 0.059 μg/L), and trichloroethylene (TCE; ND to 2.89 μg/L). In addition, 1,1-dichloroethene (1,1-DCE) was detected in one sample (VP13-15') at a concentration of 0.118 μg/L.

#### Conclusions

The following conclusions have been made based on the shallow soil and soil gas sample results:

- Concentrations of Title 22 Metals and SVOCs in soil are below the Environmental Protection Agency's, Pacific Southwest Region 9, Regional Screening Levels (RSLs) developed for a commercial/industrial scenario.
- Concentrations of OCPs in soil are below the California Environmental Protection Agency
  (Cal/EPA), Office of Environmental Health Hazard Assessment (OEHHA), residential and
  commercial/industrial California Human Health Screening Levels (CHHSLs), with the exception of
  toxaphene detected in one sample (B16-3'; 2,400 μg/kg), which exceeded the
  commercial/industrial CHHSL of 1,800 μg/kg.
- Concentrations of TPH detected in soil are below the Los Angeles California Regional Water
  Quality Control Board's (LARWQCB) maximum soil screening levels above drinking water aquifers
  greater than 150 feet bgs (LARWQCB, Table 4-1, May 1996) for TPH as gasoline (1,000 mg/kg),
  TPH as diesel (10,000 mg/kg), and TPH as motor oil (50,000 mg/kg).
- Concentrations of VOCs detected in soil gas are below the Cal/EPA (2010) CHHSLs for shallow soil gas (engineered fill) in a commercial/industrial land use scenario, for carbon tetrachloride (0.21 μg/L), PCE (1.6 μg/L), and TCE (4.4 μg/L). No CHHSLs are documented by Cal/EPA for the VOCs 1,1-DCE, Freon 113, and chloroform in soil gas.

It should be noted that the RSLs, CHHSLs, and Maximum Soil Screening Levels have been used as a general comparison, and are not regulatory standards and/or acceptable concentrations. These levels are used as benchmark values to determine whether further assessment and evaluation of the constituents detected in soil and soil gas, are required for the Site.

#### Recommendations

Based on analytical data, and the findings of this investigation, additional assessment work is not warranted at this time. However, any unknown subsurface structures or potentially contaminated soil encountered during site demolition and construction should be investigated for potential hazardous substances impacts to the property.

Additional assessment around sample location B16 at 3 feet bgs (B16-3') may be warranted in order to define the lateral and vertical extent of OCP (toxaphene) impacts in the area as necessary, and where disturbance of shallow soil in that area is anticipated during any site redevelopment activities.

## 1 INTRODUCTION

Alta Environmental, on behalf of the City of Los Angeles Department of Water and Power (LADWP), has prepared this Surface Soil and Soil Gas Sampling Report for the Tyrone Property (Site), a 17 acre property located at 7600 Tyrone Avenue, Van Nuys, California. A Site Location Map and Site Layout Map are provided as Figures 1 and 2, respectively.

The primary objective of the investigation was to assess the current surface soil conditions at the Site for potential chemicals of concern, including Title 22 Metals, organochlorine pesticides (OCPs), polychlorinated biphenyls (PCBs), total petroleum hydrocarbons (TPH), semivolatile organic compounds (SVOCs), and volatile organic compounds (VOCs). A Soil Sampling and Analysis Plan (Alta Environmental, April 26, 2013) was completed and submitted to the LADWP for review. In addition, an investigation was conducted in the vicinity of the onsite structures to assess the current soil gas conditions at the Site for potential VOC impacts. The LADWP is considering acquisition of the Site.

## 2 BACKGROUND

## 2.1 Site Description

The Site is located at 7600 Tyrone Avenue, in Van Nuys, California. A Site Location Map is presented as Figure 1. The eastern portion of the Site consists of an approximately 4 acre vacant lot that is unpaved. The remaining western portion of the Site was under demolition and construction activities by the owner at the time of the investigation. A Site Layout Map is presented as Figure 2.

The Site is currently unoccupied but was previously developed with a bioscience laboratory on the western and central section that consisted of nine buildings, parking areas, facility equipment, and chemical and hazardous material storage areas. The eastern portion of the Site contained a vacant field (approximately four acres) containing an abandoned residential-type dwelling, bunny house, construction equipment, and construction material storage areas. The vacant field was also used as a farm for laboratory animals. Historical uses at the Site include agricultural activities up to 1965, when the initial building construction began at the Site.

## 2.2 Previous Site Investigations

Past environmental investigations at the Site included a Phase I Environmental Site Assessment (ESA) prepared for Quest Diagnostics, Inc. (ODIC, October 22, 2010), a Phase I ESA prepared for Shubin-Nadal Realty Investors (AMEC, August 22, 2012a), and a Screening Level Phase II Investigation prepared for Shubin-Nadal Realty Investors (AMEC, September 28, 2012b).

Based on the results of the Phase I ESAs (ODIC, 2010 and AMEC, 2012a) and Screening Level Phase II Investigation (AMEC, 2012b) the following conclusions were made:

The soil gas data do not suggest a significant release has occurred at the site that would require
mitigation for commercial development. Soil sample data suggest metals are not present at
concentrations indicative of environmental impact and generally are consistent with typical background
concentrations. The few low concentrations of VOCs and relatively low and heavier end hydrocarbons

detected in shallow soil do not suggest significant impacts are present in the areas investigated (AMEC, 2012b).

Based on information obtained from other properties in the general site vicinity of the Site, the
anticipated depth to groundwater beneath the site is assumed to be between 200 and 250 feet below
ground surface (bgs) (Regional Water Quality Control Board's [RWQCB's] online Geotracker
database).

## 3 REGIONAL GEOLOGY AND HYDROGEOLOGIC SETTING

The following Site geologic and hydrogeologic setting information has been adapted from AMEC's Phase I Environmental Site Assessment Report (AMEC, 2012a).

## 3.1 Geologic Setting

The subject property is located in the San Fernando Valley Groundwater Basin (SFGWB). This basin is bounded on the north and northeast by the San Gabriel Mountains, the north and northwest by the Santa Susana Mountains, on the south by the Santa Monica Mountains and Chalk Hills, on the west by the Simi Hills, and the east by the San Rafael Hills (California Department of Water Resources [CDWR], 2003). Water bearing units within the SFGWB consist of the lower Pleistocene Saugus Formation, and Pleistocene and Holocene age alluvium.

Alluvium of Holocene age consists mainly of coarse-grained unsorted gravel and sand deposited by alluvial fans that originate in the surrounding mountains and hills (CDWR, 2003). Maximum thicknesses throughout the basin range from 100 feet in the north to 400 feet in the east to 800 feet in the west and a maximum thickness of 900 feet near Burbank, California (CDWR, 2003). Pleistocene age alluvium is dominated by highly permeable, unconsolidated coarse-grained alluvial fan deposits interspersed with lower permeability paleosols (CDWR, 2003).

The Saugus Formation is made up of shallow and continental marine deposits; mainly conglomerates, sands, silts, and clays (CDWR, 2003). This formation is between 2000 and 3000 feet thick in the western and eastern margins of the basin, with its greatest thickness in the center of the basin around 6,400 feet. There are many structural features within the San Fernando Valley Basin, especially on the north side of the basin; however, there is only one that is near the subject property. The closest feature is the Northridge Hills fault, which trends northwest to southeast and is located approximately 2.4 miles northwest of the subject site (AMEC, 2012a).

During the soil and soil gas sampling conducted on May 28, 2013 through June 12, 2013, soils encountered by Alta Environmental included poorly graded fine grained sands, silty sands, sandy silts, and silts.

## 3.2 Hydrogeologic Setting

The general basin trend in groundwater flow is east-southeast towards the Los Angeles Narrows and into the Central Subbasin of the Coastal Plain of Los Angeles Basin with local depth to water of approximately 200 feet bgs (ULARA, 2012).

No groundwater wells were identified at the site; however, AMEC identified one groundwater well at 7777 Lemona Avenue and two wells at 7803 Lemona Avenue in Van Nuys, all of which are located between ½ to

% mile west of the site (ENSR, 2005). Depth to groundwater in these wells was measured at approximately 250 feet bgs on May 10, 2012 with a reported groundwater flow direction to the southeast. Surface elevations at the Lemona Avenue sites (approximately 779 feet above mean sea level [msl]) are similar to the subject property (770 msl); therefore depth to groundwater at the subject property is expected to be within a similar range at greater than 200 feet bgs (AMEC, 2012a).

## 4 SURFACE SOIL SAMPLING AND SOIL GAS INVESTIGATION

## 4.1 Pre-Field Activities

The following was conducted prior to the field investigation activities:

- A site-specific health and safety plan (HASP) was prepared in general accordance with the guidelines set forth in Title 8 of the California Code of Regulations (CCR), Section 5192 (8 CCR 5192), and Title 29 of the Code of Federal Regulations (CFR) Part 1926.650 (29 CFR 1926.650). All field personnel reviewed and signed the HASP prior to beginning the field work.
- Underground Service Alert (USA) was notified on May 3, 2013, a minimum of 48-hours prior to the start
  of the field sampling activities (USA ticket # A31231015-00A).

## 4.2 Geophysical Survey

On May 6, 2013, through May 17, 2013 Alta Environmental contracted with Spectrum Geophysics to perform a geophysical survey of the northeast portion of the Site (approximately 1 acre) and clearance of the soil gas boring locations around the vicinity of the existing buildings in the western portion of the Site.

During the geophysical survey of the northeast portion of the Site, an EM-61 high-sensitivity metal detector was used in an effort to identify areas where metallic objects (ie. USTs, metal debris, and conduits) may have been buried. Once identified, these EM-61 anomalies were investigated further using GPR and EM-utility locating methods.

A total of fifteen EM-61 anomalies were detected in the subsurface throughout the Site. The anomalies appeared to be associated with various buried construction debris and long piping runs, including the storm drain channel running along the northern boundary of the property. Various linear trending anomalies (water/sewer and gas connections) were also identified throughout the survey area with the shallow metal detector and GPR units.

It should be noted that the location of subsurface objects and utilities is dependent upon the recognition of physical phenomena at the ground surface. These phenomena can be magnetic fields or electro-magnetic waves that give rise to a surface expression which in turn is interpreted as representative of subsurface objects. These waves, however, may be attenuated and/or distorted by a number of factors including soil moisture, corrosion, and proximity to other surface and subsurface facilities. At the time of the survey, various surface interferences, including soil stockpiles, stockpiled construction debris, metallic debris, reinforced concrete pads, and metal fencing, existed at the Site. A copy of the geophysical survey report is provided as Appendix A.

## 4.3 Soil Matrix Sampling and Analysis

On May 28 and 29, 2013, a total of 30 shallow borings (B1 – B30) were drilled at the Site. All soil borings were continuously cored from surface to the terminus depth of 3 feet bgs using a direct-push drill rig. Soil matrix samples were collected from each boring at 1, 2, and 3 feet bgs using a core sampler lined with acetate sleeves. Soil boring locations are presented in Figure 3 (Boring Location Map).

Following sample collection, the sample containers were properly capped, sealed, labeled, and stored in a chilled ice chest for transport under chain-of-custody documentation for analysis or archiving to LADWP's State of California-certified laboratory (Certificate No. 1207) located in Los Angeles, California. All soil samples designated for volatile analysis were preserved using in-field preservation kits in accordance with EPA Method 5035. The 1 and 3 foot samples from each boring were variously analyzed for Title 22 Metals by EPA Method 6010B, OCPs by EPA Method 8081A, PCBs by EPA Method 8082, TPH by EPA Method 8015M, SVOCs by EPA Method 8270C, and VOCs by EPA Method 8260B. The shallow soil sampling and analysis plan is presented as Table 1.

Analytical results for soil and soil gas sampling are provided in Section 5 (Analytical Results). The laboratory analytical report and chain-of-custody documentation for the surface soil samples are presented in Appendix B.

## 4.4 Soil Gas Sampling and Analysis

On May 30 and 31, 2013 soil gas probes were installed at 15 boring locations (VP1 through VP15) at 5 and 15 feet bgs. On June 4 and 5, 2013, the soil gas probes were sampled and analyzed by Jones Environmental, Inc.'s on-site mobile laboratory. Samples were not collected from gas probes at VP4 and VP5 due to inaccessibility from stockpiled demolition debris. On June 12, 2013, soil gas probes were installed in boring location VP16 in the vicinity of the former septic tank/cesspool at 5 and 15 feet bgs. Following probe installation and a minimum 2 hours of equilibration time, the gas probes at VP16 were sampled using SUMMA® canisters and analyzed by the Jones Environmental fixed laboratory.

Soil Gas boring locations are presented in Figure 3. The gas probe installation, sampling, and analysis are summarized as follows:

**Probe Installation:** At each boring location, soil gas probes were installed at five (5) and 15 feet bgs. Each soil gas probe was placed within a one-foot sand pack. One foot of dry granular bentonite was placed on top of each sand pack to preclude the infiltration of hydrated bentonite grout. The boreholes were then grouted between probes and to the surface with hydrated bentonite. Nylaflo® tubing (¼ inch) was connected from the gas point to the surface. The end of the tubing was labeled with the gas well number, depth, and date and time of construction, and a three-way valve was installed to eliminate ambient air diffusion into the well.

Purge Volume Test: A three-volume purge test (one [1], three [3], and ten [10] purge volumes) was conducted at sampling location VP3-15' to establish the optimal purge volume to be used for the probes in accordance with the Department of Toxic Substances Control (DTSC) and Los Angeles/San Francisco Regional Water Quality Control Boards (RWQCB) Advisory – Active Soil Gas Investigations (April 2012) protocol. The purge flow rate was approximately 200 milliliters per minute (mL/min). Based on the purge volume test, the optimal purge volume was determined to be one (1) due to the highest detections of VOCs.

**Sample Collection:** Soil gas samples were collected from each probe following the removal of the appropriate purge volume in 100-milliliter glass air-tight syringes or SUMMA canisters. The sample syringes were not exposed to any sunlight that may degrade light-sensitive VOCs. Soil gas samples were collected at a sampling rate of 200 ml/min or less. The samples were immediately transferred to the on-site mobile laboratory for direct injection into a gas chromatograph, or transported to the fixed laboratory for analysis in accordance with the procedures presented in the DTSC and Los Angeles/San Francisco RWQCB's *Advisory – Active Soil Gas Investigations (April 2012)*, which are consistent with EPA Method 8260B. All soil gas samples collected were documented on a chain-of-custody form for the soil gas analysis.

**Leak Test:** A leak test was conducted at each soil gas probe location to determine whether leakage was present. A mixture of n-propanol and n-pentane was used as the source of the tracer compound. The tracer gas compound was not detected in any of the soil gas samples.

**Mobile Laboratory and Fixed Laboratory Analysis:** The soil gas samples collected for this investigation were analyzed for VOCs by EPA Method 8260B by an on-site mobile and fixed laboratory. The soil gas samples included 28 primary samples, two (2) purge volume samples, and three (3) field replicates for a total of 33 soil gas samples. The soil gas sampling and analysis plan is presented as Table 2.

The laboratory analytical report and chain-of-custody documentation for the soil gas samples are presented in Appendix B.

## 4.5 Equipment Decontamination

All reusable drilling and sampling equipment were cleaned before each use utilizing a three-bucket wash consisting of a non-phosphate detergent wash, tap water, and distilled water.

### 4.6 Field Observations

No odors or staining were observed in the soil samples collected during the investigation. In addition, no (0.0 parts per million [ppm]) photo-ionization detector (PID) readings were observed in the screened soil samples. No groundwater was encountered in the borings to a maximum depth of 15 feet bgs.

## 4.7 Site Geology

The soils encountered during the surface soil sampling and soil gas probe installation consisted of poorly graded fine grained sands, silty sands, sandy silts, and silts. Soil borings were logged continuously using the Unified Soils Classification System (UCSC) and screened with a PID calibrated to 50 parts per million (ppm) as hexane. The boring logs for each soil boring are provided in Appendix C.

## 5 ANALYTICAL RESULTS

The following surface soil sample results are presented in milligrams per kilogram (mg/kg) and micrograms per kilogram ( $\mu$ g/kg) as identified in Tables 3 through 8. The following soil gas sample results are presented in micrograms per liter ( $\mu$ g/L) as identified in Table 9. Some data have been qualified by the laboratory as "J-flagged" indicating that the detected concentration is an estimated value between the method detection limit (MDL) and the practical quantitation limit (PQL).

No VOCs or PCBs were detected in any of the surface soil samples submitted for analysis.

- Surface soil samples variously exhibited detected concentrations of:
  - Title 22 Metals including antimony (not detected above the laboratory reporting limit [ND] to 4.2J mg/kg), barium (99 to 300 mg/kg), cadmium (1.8J to 4.1 mg/kg), chromium (10 to 23 mg/kg), cobalt (7.8 to 21 mg/kg), copper (7.7J to 22 mg/kg), lead (6.7 to 42 mg/kg), molybdenum (ND to 0.50J), nickel (12.3 to 24 mg/kg), vanadium (19 to 38 mg/kg), zinc (36 to 124 mg/kg), and mercury (ND to 0.048 mg/kg). In addition, silver was detected in one sample (B22-1') at 7.4J mg/kg;
  - SVOCs including benzo(g,h,i)perylene (ND to 0.11J mg/kg), butyl benzyl phthalate (ND to 0.29J mg/kg), and indeno(1,2,3-cd)pyrene (ND to 0.17J mg/kg). In addition, dibenzo(a,h)antrhacene and pentachlorophenol were detected in one sample (B21-1') at 0.099J mg/kg and 0.39J mg/kg, respectively;
  - OCPs including 2,4-DDD (ND to 36 μg/kg), 2,4-DDT (ND to 190 μg/kg), 4,4-DDE (ND to 740 μg/kg), 4,4-DDT (ND to 270 μg/kg), beta-hexachlorocyclohexane (beta-BHC; ND to 42 μg/kg), and toxaphene (ND to 2,400 μg/kg); and
  - o TPH as total extractable petroleum hydrocarbons (TEPH; ND to 60.6 mg/kg [as motor oil]);
- Soil gas samples exhibited detected concentrations of VOCs including carbon tetrachloride (ND to 0.035 μg/L), chloroform (ND to 0.896 μg/L), Freon 113 (ND to 2.82 μg/L), tetrachloroethylene (PCE; ND to 0.059 μg/L), and trichloroethylene (TCE; ND to 2.89 μg/L). In addition, 1,1-dichloroethene (1,1-DCE) was detected in one sample (VP13-15') at a concentration of 0.118 μg/L.

### 6 CONCLUSIONS

The surface soil and soil gas investigation completed at the Site between May 28, 2013 and June 12, 2013 included the advancement of 30 surface soil borings and 16 soil gas borings. Based on the shallow soil sample and the soil gas sample analytical results, Alta Environmental makes the following conclusions:

- Concentrations of Title 22 Metals and SVOCs in soil are below the California Environmental Protection Agency's (CalEPA, Region 9) Regional Screening Levels (RSLs) developed for a commercial/industrial scenario.
- Concentrations of OCPs in soil are below the Cal/EPA, Office of Environmental Health Hazard
  Assessment (OEHHA), residential and commercial/industrial California Human Health Screening
  Levels (CHHSLs), with the exception of toxaphene detected in one sample (B16-3'; 2,400 μg/kg),
  which exceeded the commercial/industrial CHHSL of 1,800 μg/kg.
- Concentrations of TPH detected in soil are below the Los Angeles California Regional Water
  Quality Control Board's (LARWQCB) maximum soil screening levels above drinking water aquifers
  greater than 150 feet bgs (LARWQCB, Table 4-1, May 1996) for TPH as gasoline (1,000 mg/kg),
  TPH as diesel (10,000 mg/kg), and TPH as motor oil (50,000 mg/kg).
- Concentrations of VOCs detected in soil gas are below the Cal/EPA (2010) CHHSLs for shallow soil gas (engineered fill) in a commercial/industrial land use scenario, for carbon tetrachloride (0.21 μg/L), PCE (1.6 μg/L), and TCE (4.4 μg/L). No CHHSLs are documented by OEHHA/CalEPA for the VOCs 1,1-DCE, Freon 113, and chloroform in soil gas.

It should be noted that the RSLs, CHHSLs, and Maximum Soil Screening Levels have been used as a general comparison, and are not regulatory standards and/or acceptable concentrations. These levels are used as benchmark values to determine whether further assessment and evaluation of the constituents detected in soil and soil gas, are required for the Site.

## 7 RECOMMENDATIONS

Based on analytical data, and the findings of this investigation, additional assessment work is not warranted at this time. However, any unknown subsurface structures or potentially contaminated soil encountered during site demolition and construction should be investigated for potential hazardous substances impacts to the property.

Additional assessment around sample location B16 at 3 feet bgs (B16-3') may be warranted in order to define the lateral and vertical extent of OCP (toxaphene) impacts in the area as necessary, and where disturbance of shallow soil in that area is anticipated during any site redevelopment activities.

## 8 ASSUMPTIONS AND LIMITATIONS

This report was prepared exclusively for use by the City of Los Angeles Department of Water and Power, and may not be relied upon by any other person or entity without Alta Environmental's express written permission. The information, conclusions and recommendations described in this report apply to conditions existing at certain locations when services were performed and are intended only for the specific purposes, locations, time frames and project parameters indicated. Alta Environmental cannot be responsible for the impact of any charges in environmental standards, practices or regulations after performance of services.

In performing our professional services, we have applied present engineering and scientific judgement and used a level of effort consistent with the current standard of practice for similar types of studies.

As applicable, Alta Environmental has relied in good faith upon representations and information furnished by individuals with respect to operations and existing property conditions, to the extent that they have not been contradicted by data obtained from other sources. Accordingly, Alta Environmental accepts no responsibility for any deficiencies, omissions, misrepresentations, or fraudulent acts of persons interviewed.

Alta Environmental will not accept any liability for loss, injury claim, or damage arising directly or indirectly from any use or reliance on this report. Alta Environmental makes no warranty, expressed or implied.

This report is issued with the understanding that the client, the property owner, or its representative is responsible for ensuring that the information, conclusions, and recommendations contained herein are brought to the attention of the appropriate regulatory agencies, as required.

OCPs = Organochlorine Pesticides

MDL = Method Detection Limit

MRL = Method Reporting Limit

μg/kg = mkrograms per kilogram

ND = Not detected at or above the MDL

NA = Information not available

- = Not applicable

\*California Human Health Screening Levels (CHHSLs) for residential and commercial settings are provided for detected concentrations of OCPs

Indicates concentration exceeds the commercial/industrial CHHSL

### NOTES:

ND = Indicates constituents not detected; below MDL

MDL = Method Detection Limit

PQL = Practical Quantitation Limit

J = Concentration above the MDL but below the PQL

TEPH = total extractable petroleum hydrocarbons

TPH = total petroleum hydrocarbons

GRO = gasoline range organics

DRO = diesel range organics

mg/kg = milligrams per kilogram

- = information not available

<sup>\*</sup> The LARWQCB Maximum Soil Screening Levels are are provided for TPH in soil above drinking water aquifers greater than 150 bgs (LARWQCB Table 4-1, May 1996)
